#### **EXECUTIVE SUMMARY**

2 The Saipan Lagoon Aquatic Ecosystem Restoration Study is being conducted under the United

- 3 States Army Corps of Engineers (USACE) Continuing Authorities Program authorized in
- Section 206 of the Water Resources Development Act of 1986. 4 The cost sharing project
- 5 proponent, the Commonwealth of the Northern Mariana Islands (CNMI) Coastal Resources
- 6 Management Office (CRMO) is responsible for providing 35% of the project cost. The statutory
- 7 limit for Federal participation under Section 206 authority is five million dollars.
- 8 The purpose of this study is to identify and evaluate engineering solutions to restore the degraded
- 9 lagoon aquatic habitat. A number of environmental/biological investigations and studies were
- 10 conducted in order to adequately establish baseline environmental conditions within the lagoon
- and to assess the effectiveness of future remedial measures to be implemented in the watershed. 11
- 12 The results of these studies indicate that inner lagoon habitats are affected by increased sediment
- 13 and nutrient load entering the lagoon via stormwater runoff within the study area. Increased
- 14 sediment and nutrient load has led to a shift in macroalgae-dominant marine system where less
- 15 seagrass and coral species are able to thrive in. Seagrass and coral reef systems provide habitats
- 16 for numerous species of fish and invertebrates that compose a healthy marine ecosystem.
- 17 Urbanization of the inland watershed area that has occurred over the past twenty years has
- 18 dramatically increased the amount of sediment, nutrient, and contaminants discharged into 19 Saipan Lagoon via stormwater runoff. The probable future increase in urbanization of this area
- 20 would likely further degrade and have a deleterious impact on the aquatic ecosystem structure of
- 21 the lagoon.

- 22 Detention basins were considered at three locations: near the China House restaurant between
- 23 Middle Road, across from the Pizza Hut building, and Beach Road (China House site); at the
- 24 northwestern corner of the intersection of Quartermaster Road and Middle Road (Quartermaster
- 25 site); and at a site on Middle Road approximately 200 feet north of Commonwealth Road (Cock
- 26 Fight Arena site) to address the overall project objective of reducing sediment and nutrient loads
- 27 entering the lagoon. The proposed detention basins are expected to capture runoff from areas
- 28 located inland or upslope from the sites, allowing sediment and contaminants to settle out, and
- 29 then discharge the stormwater to the lagoon in a more controlled manner via underground piping.
- 30 The detention basins would significantly alleviate flooding along Beach Road as well as capture
- 31 the large volumes of fast-moving sheet flow prior to it reaching or crossing Beach Road, and
- 32 thereby significantly reduce the transfer of nutrients, sediment, and pollutants associated with the
- 33 upper watershed from being washed into Saipan Lagoon.
- 34 Based on the assumptions that any or all of the three sites could be developed concurrently, at the
- 35 no-build, two-year, five-year, or 10-year storm design level, 64 different plan combinations were
- evaluated based on their cost and expected level of benefits. Following an evaluation of all 36
- 37 combinations, based on project cost and expected output, CRMO selected a single two-year
- 38 design level detention basin at the Cock Fight Arena site with an estimated total project cost of
- 39 \$8,451,000. The selected plan will restore an estimated 70.3 acres of lagoon habitat.

#### 1. INTRODUCTION

- 2 This Detailed Project Report (DPR) has been prepared for Saipan Lagoon, Saipan,
- 3 Commonwealth of the Northern Mariana Islands (CNMI). This report includes an assessment of
- 4 the lagoon based on the compilation of data derived from field studies conducted during the
- 5 Phase I and II of the Saipan Lagoon Aquatic Ecosystem Restoration Study, ongoing local
- 6 authority lagoon studies, and review of historical records. An Environmental Assessment (EA)
- 7 prepared concurrently with this report (Appendix A) includes a detailed analysis of the potential
- 8 environmental impacts of the preferred alternative selected in this DPR.

#### 9 1.1 STUDY PURPOSE

1

- 10 A combination of increasing population and urbanization of the West Takpochao watershed over
- the past 70 years has led to degradation of the aquatic ecosystem that makes up Saipan Lagoon.
- 12 Indicators of this degradation include changes in the density, distribution, and composition of
- seagrass communities in nearshore waters; high abundance of seasonal macro-algal growth;
- decrease in nearshore lagoon fish; degraded lagoon corals; and increased frequency of water
- 15 quality standard violations in nearshore recreational waters. Increased sediment and nutrient
- load has led to a shift in macroalgae-dominant marine system where less seagrass and coral
- species are able to thrive in. Seagrass and coral reef systems provide habitats for numerous
- species of fish and invertebrates that compose a healthy marine ecosystem. The probable future
- increase in urbanization of this area would likely further degrade and have a deleterious impact
- on the aquatic ecosystem structure of the lagoon.
- 21 Recent manifestations of lagoon degradation are of concern not only because of the deterioration
- of natural resources supported by the lagoon, but also because degradation has progressed to the
- point that the aesthetic and recreational utility of the lagoon has been negatively impacted. This
- 24 is of substantial concern considering that the lagoon is a vital component of the tourism industry
- 25 that accounts for the majority of the local economy in Saipan.
- 26 Indicators of degradation will be discussed in detail in the following sections, together with the
- 27 desired outcomes of future restoration activities, and the best possible restoration alternative for
- 28 the study area. The purpose of this study is to: (1) determine current environmental baseline
- 29 conditions of Saipan Lagoon, (2) to develop restoration alternatives, and (3) to select an
- 30 environmentally sensitive and economically feasible restoration alternative that would best
- 31 restore the degraded aquatic ecosystem structure, function, and dynamic processes to a less
- 32 degraded and more natural condition.

33

#### 1.2 STUDY AUTHORIZATION

- 34 The Saipan Lagoon Aquatic Ecosystem Restoration Study is being conducted under the United
- 35 States (US) Army Corps of Engineers' (USACE) Continuing Authorities Program authorized in
- 36 Section 206 of the Water Resources Development Act of 1996. Under this program, the USACE
- is responsible for 65 percent (%) of the total project cost (planning, design, and construction).
- 38 As the cost sharing project proponent, the CNMI is responsible for providing 35% of the project
- 39 cost. The statutory limit for Federal participation under Section 206 authority is five million
- 40 dollars. In addition to its cost sharing obligation, the CNMI is responsible for providing all land,

- 1 easements, rights-of-way, relocation, and disposal areas (LEERD) required for project
- 2 implementation, and operation and maintenance of the completed project. The CNMI may
- 3 receive credit towards its share of project cost for the value of the LEERD required for the
- 4 project. Additionally, the CNMI will receive a \$200,000 cost sharing waiver for planning and
- 5 design/construction as allowed by Section 1156 of the Water Resources Development Act of
- 6 1986.

#### 1.3 STUDY SPONSER

- 8 The CNMI Coastal Resources Management Office (CRMO) is the local study sponsor
- 9 (proponent) and represents the CNMI Government's interest on the Project Delivery Team
- 10 (PDT).

#### 11 1.4 LOCAL REGULATORY AUTHORITY

- 12 The CNMI has promulgated a number of regulations over the past 15 years to protect the
- 13 environment. Basic environmental rights can be found in the CNMI constitution that states in
- 14 Article I, Section 9, that each person has the right to a clean and healthful public environment.
- 15 The CNMI Division of Environmental Quality (DEQ) was formed "to develop and administer
- programs, including, where appropriate, a system of standards, permits, or prohibitions, to
- prevent or regulate activities concerning the discharge of pollutants to the air, land, water,
- wetlands, and submerged lands." The DEQ has set forth regulations governing earthmoving
- 19 activities in order to prevent soil erosion and to minimize pollution of marine, surface or
- 20 groundwater resources. Although the National Pollutant Discharge Elimination System
- 21 (NPDES) program has not been delegated to the CNMI, DEQ issues Section 401 Water Quality
- 22 Certifications to any project that may affect water quality. Section 401 Water Quality
- 23 Certifications are issued for all projects involving discharges, dredging, or any activity involving
- 24 wetlands. This CNMI permitting process is closely linked to the USACE Section 404 permitting
- 25 program.
- 26 The CRMO Program was developed to manage all activities within areas designated as Areas of
- 27 Particular Concern (APCs), including the shoreline (extending to 150 feet inland), lagoon and
- 28 reefs, wetlands, and industrial areas surrounding seaports. The Coastal Resources Management
- 29 Act (outlined in CNMI Public Law 3-47) was established to coordinate island development
- 30 management and specifies policies and rules that regulate activities with the potential to affect
- 31 the Saipan's resources. These resources are broadly defined in the Coastal Resources
- 32 Management Act and include marine water and associated resources, groundwater, wetlands,
- watersheds, and certain designated APCs. Prior to the initiation of any large development in the
- CNMI, the developer must obtain a CRMO major siting permit. The CRMO permitting process
- provides all of the appropriate government agencies an opportunity to inform the developer of
- 36 the various permitting requirements and general areas of concern for the proposed project.
- 37 CRMO also has an active monitoring and enforcement section that is responsible for monitoring
- activities within the APCs.
- 39 Any open discharges into waters or wetlands require a NPDES Permit from the US
- 40 Environmental Protection Agency (EPA) Region 9 Office located in San Francisco, California.
- 41 For example, the CNMI government holds NPDES permits for the discharge of treated sewage

- 1 into two locations offshore of Saipan. NPDES permits generally require extensive monitoring
- 2 and reporting, and a DEQ Water Quality Certification must also be obtained.
- 3 The CNMI Marine Monitoring Team (MMT) consists of members from the DEQ, CRMO, and
- 4 the CNMI Division of Fish and Wildlife (DFW). This interagency MMT was initially
- 5 established in 1997 to aid in understanding the current conditions of coral reefs and coral reef
- 6 resources in the CNMI. The first State of the Reef Reports prepared by DEQ for Saipan and
- 7 Rota Island (Houk, 1999 and 2000) document the baseline conditions of the reef and marine
- 8 ecosystems, and are used for future assessments and regional management recommendations. It
- 9 is the goal of the MMT to continue this long-term monitoring program to continually assess reefs
- and aquatic resources of the CNMI.

#### 1.5 ONGOING AND PRIOR STUDIES, REPORTS, PROJECTS

- 12 A number of environmental/biological investigations and studies have been conducted, or are
- ongoing, on Saipan in the general vicinity of Saipan Lagoon and are detailed in this study's
- 14 Phase I Report (Appendix B). A review of these studies identified a number of additional studies
- 15 needed to adequately establish baseline environmental conditions within the lagoon. These
- additional studies included the following and were conducted in order to fill the data gaps for the
- study area so that the effectiveness of future remedial measures to be implemented in the
- watershed and/or the lagoon can be accurately evaluated:
- stormwater quality investigation;
  - lagoon sediment physical and chemical parameter characterization;
- historical assessment of lagoon from aerial photographs;
- inshore lagoon seagrass and associated fauna survey;
- inventory of potentially contaminating activities (PCAs) in the watershed;
- groundwater investigation;
- hydrologic study of runoff processes in the watershed;
- sediment delta surveys; and
- lagoon water quality investigation.
- 28 The results of these baseline monitoring studies are included in Appendix C and summarized in
- 29 Section 4 of this report.

- 30 DEQ and the MMT have initiated two large-scale bio-criteria monitoring programs. Both of
- 31 these are very different from EPA funded bio-criteria monitoring programs in the US mainland.
- 32 Tropical marine systems are much more dynamic and harbor very different organisms than
- 33 terrestrial fresh water systems or even marine water systems in cold environments. Bio-criteria
- 34 programs set forth in the US mainland fail to provide useful techniques for application in the
- 35 CNMI. The first monitoring effort is the Saipan Lagoon Monitoring Program (DEQ and CRMO
- only), and the other is the CNMI Nearshore Reef Monitoring Program (DEQ, CRMO, and
- 37 DFW). The goal of these programs is to gather continuous data from marine systems that are

- 1 affected by water quality concerns (e.g., watershed drainages, sewage pump failures and outfalls,
- 2 and other sources of point and nonpoint source pollution). Currently, the Saipan Lagoon
- 3 monitoring effort has completed an inventory of one region of the lagoon: the study area
- 4 (extending from Quartermaster Road to Garapan Fishing Base).
- 5 DEQ has also recently completed a Section 305(b) Water Quality Assessment Report for the
- 6 CNMI (DEQ, 2010). This report was written following guidance detailed in Section 305(b) of
- 7 the Clean Water Act (CWA) and allowed determination of the following issues: (1) whether US
- 8 waters meet water quality standards, (2) the progress made in maintaining and restoring water
- 9 quality, and (3) the extent of remaining problems in the CNMI. On shore, the Safe Drinking
- 10 Water program began implementing the volatile organic compound (VOC) monitoring
- 11 requirement, as outlined in the CNMI Drinking Water Regulations in January 2000. Public
- water systems within the CNMI will be required to perform VOC testing in order to come into
- 13 compliance with these regulations.

#### 2. STUDY AREA DESCRIPTION

- 2 This section provides a description of the study area location as well as site history, including a
- 3 historical comparison of population growth in the study area. A more detailed description of
- 4 characteristics and components of the study area is included in the Phase I Report (Appendix B).

#### 5 2.1 STUDY AREA LOCATION

- 6 The study area encompasses the southern portion of the West Takpochao watershed and extends
- 7 from Quartermaster Road to the northern boundary of the Hafa Adai Hotel in the village of
- 8 Garapan (Figure 1). The study area includes the entire inland watershed that contributes
- 9 groundwater and surface water runoff to the approximately two-mile length of shoreline, as well
- as the adjacent offshore lagoon area extending out approximately 0.3 miles.

#### 2.2 STUDY AREA DESCRIPTION

- 12 The shoreline within the study area consists of a narrow sand beach. The beach mainly consists
- of loose limesand with some gravel, shell, and coral rubble, over calcareous gravel and beach
- 14 rock. These sediments are primarily medium to coarse-grained and well-sorted. The beach is
- topped at the high water mark by a strip of grasses, vines, and trees, followed by a concrete
- pedestrian pathway further inland. The 2.8-mile, concrete pedestrian walking pathway meanders
- between the narrow sandy shoreline and Beach Road. Picnic facilities, numerous trees, vehicle
- turnout areas, a memorial to fishermen lost at sea (13 Fishermen Monument), a Japanese tank
- monument, and concrete defensive bunkers built by the Japanese during World War II (WWII)
- are also found along this section of shoreline. The northern boundary of the study area contains
- an earthen pier that was built by the Japanese during their occupation during WWII on the island.
- A dilapidated barge that was formerly used as a restaurant rests firmly aground just to the south
- of this earthen pier. The southern boundary of the study area is where Quartermaster Road
- 24 intersects with Beach Road. The area to the east of Beach Road contains numerous businesses
- built on private land, including restaurants, hardware and stationary stores, car lots, and several
- 26 strip malls.

1

- Beach Road is a two lane, undivided, signaled, asphalt highway that was improved by the US
- 28 military following WWII, but was not completely paved along its length until about 1985.
- 29 Middle Road runs parallel to and about a half-mile inland of Beach Road, and was improved to a
- 30 paved, four-lane, undivided, signaled asphalt highway in about 1990. Two paved roads link
- 31 these two highways, Island Power Road to the north and Quartermaster Road at the southern
- 32 boundary of the study area. A number of coral gravel surface roads leading to small commercial
- and residential buildings are present within the study area. The slope of the land becomes
- 34 steeper above Middle Road and the watershed is broken into a series of irregular hills and valleys
- 35 containing intermittent streams.
- 36 The Coastal Resources Management Commission has delineated 11 major watersheds on Saipan.
- 37 The study area is located within the West Takpochao watershed (Figure 2). This watershed
- 38 extends along the shoreline from about 500 feet south of Quartermaster Road to the area just
- 39 north of Charlie Dock at Tanapag Harbor. The watershed extends inland to the ridgeline that
- runs up to Mount Takpochao and continues on through the Capitol Hill area.

- 1 The coastal areas of the study area are vegetated with ironwood (Casuarina equisetifolia), sea
- 2 hibiscus (*Hibiscus tiliaceus*) and a number of ornamental trees with an understory dominated by
- 3 grasses and seaside morning glory (*Ipomoea pescaprae*). The inland portions of the study area
- 4 are either paved or overgrown by scrub vegetation dominated by tangantangan (Leucaena
- 5 leucocephala), ivy gourd (Coccinia grandis), and occasional ironwood and coconut trees.

#### **2.2.1** Climate

6

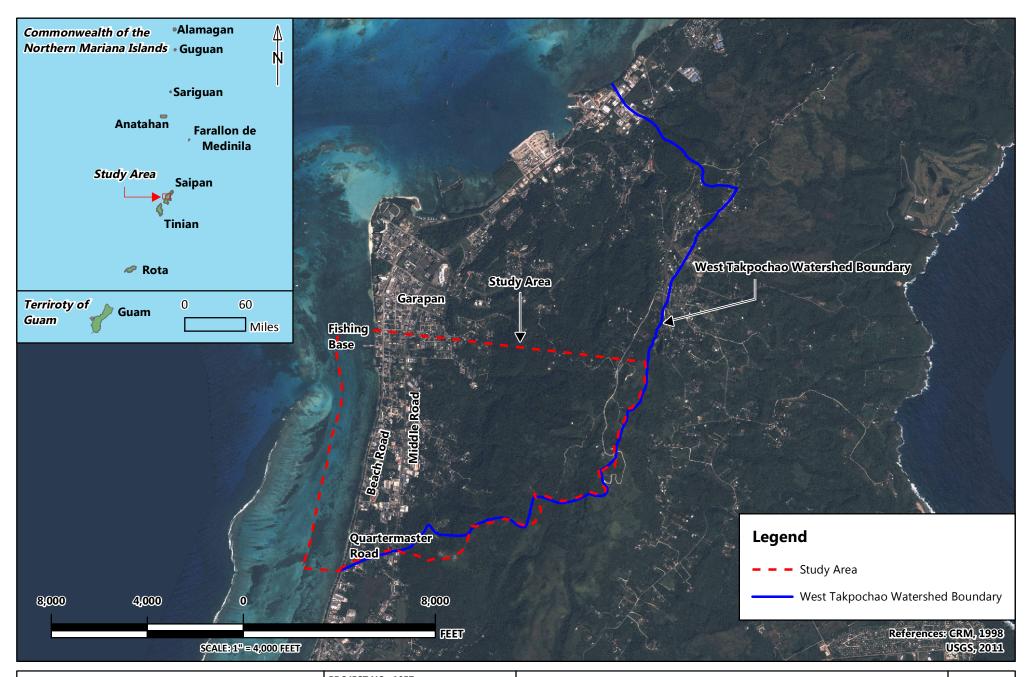

19

- 7 The climate in Saipan is warm and humid throughout the year and is classified as tropical
- 8 marine, with an average temperature between 75 to 80 degrees Fahrenheit (°F) (Van der Brug,
- 9 1985). The humidity levels are very high, with monthly averages ranging from 79 to 86%.
- 10 Typically, July to November have the highest humidity. Rainfall in the study area is seasonal
- and averages about 75 to 80 inches per year. The wet season usually extends from July through
- 12 November, followed by a dry season from December through June. Saipan experienced
- drought-like conditions during 1998, when the rainfall between January and November totaled
- roughly 41 inches, or approximately half the annual mean. Based on data collected from the
- 14 Toughly 41 inches, of approximately han the annual mean. Based on data confected from the
- weather station at Saipan International Airport from years 2007 through 2011 (Table 1), monthly average temperatures range from 79 to 83 °F. Monthly average relative humidity at the same
- station from 2007 to 2011 range from 77 to 84%. The average yearly total precipitation for years
- 18 2007 through 2011 is 73.8 inches per year.

Table 1: Summary of Weather Data at Saipan International Airport

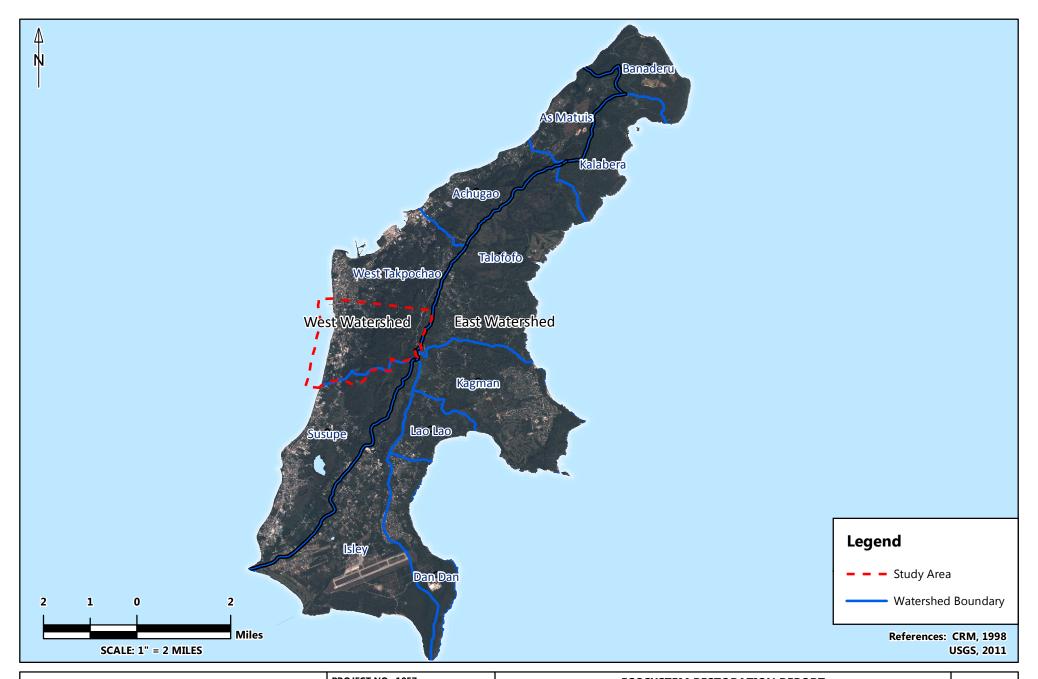

Monthly Averages for Years 2007 through 2011				
Month	Temperature (°F)  Relativ Humidi (%)		Precipitation (inches)	
January	80	77	4.2	
February	79	77	2.8	
March	79	78	3.0	
April	81	79	3.3	
May	83	77	5.6	
June	83	77	5.4	
July	82	82	7.0	
August	81	84	11.4	
September	81	84	9.4	
October	81	84	12.9	
November	81	81	5.3	
December	81	78	3.5	
Yearly Average	81	80	73.8

ECOSYSTEM RESTORATION REPORT
SAIPAN LAGOON AQUATIC ECOSYSTEM RESTORATION STUDY
WATERSHED MAP OF SAIPAN
SAIPAN, CNMI

2

- 1 The CNMI are dominated by tradewinds, which blow from the east or northeast. These winds
- 2 are the strongest and most constant during the dry season, when wind speeds of 15 to 25 miles
- 3 per hour are common. The CNMI is situated some 600 miles east of an area in the western
- 4 Pacific which is the breeding ground of cyclonic disturbances. As a result, the CNMI is in
- 5 typhoon condition four (i.e., 40 mile per hour winds are possible within 72 hours) at all times.
- 6 These cyclonic disturbances can develop quickly and sometimes unexpectedly into typhoon
- 7 force winds of 120 miles per hour or greater.
- 8 During the rainy season, the tradewinds often cease, and on some days, the weather may be
- 9 dominated by westerly moving storm systems that bring heavy showers or steady, and at times,
- 10 torrential rains. These episodic, heavy rainfall events contribute the majority of the sediment and
- surface water runoff that reaches the nearshore lagoon environment.
- 12 Table 2 shows storm frequency intensities calculated from data collected from a National
- Oceanic and Atmospheric Administration (NOAA) rain gauge station located at the Saipan
- 14 International Airport from the years 1979 through 2001 (Environet, 2003). Other rain gauges
- maintained by the United States Geological Survey (USGS) as well as NOAA are located in
- various places around the island, but the airport station has recorded the most comprehensive
- data since 1979. Data quality for recent years is poor due to missing data, uncertainty of values,
- 18 erroneous data, and other factors (NOAA, 2011).

Table 2: Average Storm Frequencies and Intensities at Saipan International Airport

Storm Frequency	Rainfall (inches per 24-hour period)	Rainfall (inches per hour)	
100-year event	16.80	4.48	
50-year event	14.87	4.06	
25-year event	12.94	3.64	
10-year event	10.33	3.06	
5-year event	8.26	2.61	
2-year event	5.14	1.93	

- Table 2 does not include two large rainfall events, Super Typhoon Kim in 1986 and Typhoon
- 21 Lynn in 1987. In addition, since the gauge station is located on the southern part of the island,
- 22 rainfall recorded at this station most likely varies from rainfall in the actual study area.
- However, this data does provide baseline conditions for the intensity and frequency of rainfall
- events in the study area.

25

#### 2.2.2 Topography and Soil

- 26 The study area is situated in the western central part of the island of Saipan. The study area
- 27 potentially receives runoff and sediments from the southern half of the West Takpochao

- 1 watershed, which extends roughly two miles inland to the limestone ridge that peaks at 1,540
- 2 feet above mean sea level (msl) on the summit of Mount Takpochao. The area between the
- 3 shoreline and Middle Road is a slightly to moderately sloping coastal plain composed of 4 unconsolidated limestone-derived sediments. The area inland of Middle Road possesses the
- 5 characteristic geomorphology of the island of Saipan with slightly to moderately sloping
- topographic plateaus separated by seaward-facing scarps of emergent limestone (Cloud et al., 6
- 7 1956).
- 8 The characteristics of the surface soils generally vary moving inland from the shoreline to the
- 9 upland areas of the watershed. The lowland areas that extend from the shoreline to just inland of
- 10 Middle Road are dominated by soils of the Chinen-Urban Land Map Unit (Young, 1989). These
- 11 soils are composed of clay loam and are highly porous, accounting for the lack of natural
- 12 streambeds or continuous drainage ways across the lowland areas. During the Japanese and
- 13 German occupations, much of these lands were in intensive agricultural use. The areas upland of
- 14 Middle Road in the vicinity of Gualo Rai are covered by soils of the Kagman-Saipan Map Unit
- 15 brown clay) while further inland the land area is dominated by (thick,
- 16 Takpochao-Chinen-Rock Outcrop Map Unit (limestone and alluvial clay wash). The
- 17 Chinen-Urban Land complex (clay loam soils) in the lowlands between Middle Road and Beach
- 18 Road is the soil unit most prone to erosion in the area. However, the largest percentage of the
- 19 sedimentation that occurs along the Beach Road drainages appears to come from quarried,
- 20 crushed limestone backfill used for road and lot surfacing, rather than from erosion of the
- 21 underlying native and disturbed soils. Extensive backfill was first used in this area during
- 22 post-WW II American military construction activities. Saipan was quickly transformed into a
- 23 major military installation, to be used as a logistical and training base for subsequent invasions of
- 24 Iwo Jima, Okinawa, and Japan. The scale of the construction was massive and few portions of
- 25 the island were left untouched (Butler and De Fant, 1991).

#### 2.2.3 Erosion

- 27 Sediment transport to lowland areas occurs naturally in all island systems. In the study area, the
- 28 amount of sediments being transported to the lagoon environment has increased in conjunction
- 29 with the spreading urbanization of the lowland areas within the watershed. The increased
- 30 number of roofs, roads, and other paved areas impervious to rain increases the amount of runoff
- 31 and tends to channel the runoff between properties. Construction activities and clearing of the
- 32 natural vegetation tend to disturb and expose the natural soils, rendering them more susceptible
- 33 to sheet and rill erosion. A reduction in natural vegetation due to increased urbanization also
- 34 limits the infiltration capacity of the substrate and exacerbates runoff and erosion capacities.
- 35 The Soil Conservation Service estimated erosion rates for Saipan soils present in the Kagman
- 36 Watershed on the eastern side of the island. The average erosion rate from the forested upper
- 37 watershed is estimated to be about three tons per acre per year while areas under construction
- may exceed rates of 20 tons per acre per year. The developed homestead area in Kagman, which 38
- 39 is situated on a relatively flat limestone plateau, yields between two to five tons of soil per acre
- 40 per year. Erosion rates for the soils present within the study area are not currently available.
- 41 However, observations made during the 2011 reconnaissance field visit of eroded gravel roads,
- 42 obvious sedimentation in storm drain gullies, and occasional lapses in implementation of best
- 43 management practice (BMP) regulations at construction sites suggest that erosion rates may be

- 1 high. An attempt to evaluate sedimentation rates within the study area was undertaken by
- 2 studying deltaic deposits along the shoreline. Results of this study are discussed in detail in
- 3 Appendix C.7.

#### 2.2.4 Regional Geology and Hydrogeology

- 5 The island of Saipan, along with the other islands of the Mariana chain, is situated in a
- 6 double-arc, convergent plate margin setting. Parts of the arc are still volcanically active,
- 7 especially to the north of Saipan. Large-magnitude, deep-focus earthquakes, and volcanism are
- 8 still common throughout the northern portion of the Mariana Islands (Meijer et al., 1982). Karig
- 9 (1971) proposed a tectonic model for the evolution of this region in which volcanic arcs were
- 10 rifted to produce remnant arcs, frontal arcs, active arcs, and interarc basins. The proto-arc
- system developed as a volcanic arc upon oceanic or interarc basin crust in late-Eocene to
- mid-Oligocene time. Part of the arc was rifted to produce the Palau-Kyushu Ridge remnant arc,
- the South Honshu Ridge active arc, and the Parace Vela and Shikoku interarc basins in the
- 13 the South Housing Ridge active are, and the Farace vela and Shikoka interare basins in the
- mid-Oligocene to late-Miocene Period. The southern portion of the South Honshu Ridge was, in
- 15 turn, rifted in late Miocene time to produce the West Mariana Ridge remnant arc, the Mariana
- 16 frontal arc, the Mariana active arc, and the Mariana Trough interarc basin. The island of Saipan
- is currently located within the Mariana frontal arc while the islands to the north are located in the
- 18 Mariana active arc.
- 19 The island-arc volcanism that created the volcanic base of the islands of the Marianas chain was
- 20 characterized by pyroclastic eruptions of andesitic and dacitic composition. The majority of the
- 21 volcanic material exposed sub-aerially on Saipan was erupted in a submarine environment as the
- 22 juvenile arc volcano steadily rose above the ocean floor. These basement volcanic rocks were
- 23 placed into four formations by Cloud et al. (1956). Three of the four volcanogenic formations
- 24 (Sankakuyama, Hagman, and Densinyama) comprise the "basement" rock encountered on
- 25 Saipan. The Fina Sisu formation volcanics were placed in the middle of the stratigraphic section
- above the Matansa limestone unit. The Sankakuyama, Hagman, and Densinyama Formations
- were assigned a mid- to late-Eocene age by Cloud et al. (1956). This age assignment has been
- 28 confirmed by subsequent K-Ar (potassium-argon) age dating conducted on lava units within
- 29 these formations, yielding dates from 35.7 to 41.4 million years before present (Meijer et al.,
- 30 1982). The Fina Sisu formation was assigned a late Oligocene age by Cloud et al. (1956) based
- on a study of the microfossils present in the marine tuff units of this formation. However, Meijer
- of a stage of the interference present in the matthe tall talls of this formation. However, interference
- 32 et al. (1982) determined a mid-Miocene age (12.9 million years) for this formation by dating an
- 33 andesite lava flow exposed in a tunnel located along As Perdido Road. This younger age is
- 34 consistent with a revised fossil age determination for the Fina Sisu formation that was previously
- 35 reported.
- 36 Saipan has undergone significant tectonic uplift as a result of the flexure of the underlying outer
- edge of the Philippine Plate in response to subduction of the Pacific Plate to the east of Saipan
- 38 along the Marianas trench. Subsequent sub-aerial exposure of the volcanic basement rock led to
- 39 erosion and reworking of the original volcanic material to produce clastic sediments, which have
- 40 become cemented to form sandstones, conglomerates, and breccias of low porosity. Tectonic
- 41 uplift of the island has also exposed thick, fringing limestone units that at elevations of up to
- 42 1,540 feet above msl on the summit of Mount Tagpochau. Thus, the island consists of an
- andesitic-dacitic volcanic core overlain by sandstones, conglomerates, and breccias, which are,

- 1 in turn, capped by limestones. At present, more than 90% of the surface of the island is currently
- 2 mantled with these limestone formations and alluvium derived from the erosion of these units.
- 3 The characteristic geomorphology of Saipan (i.e., flat to slightly sloping topographic plateaus
- 4 separated by seaward-facing scarps) has been produced by episodic, upward faulting related to
- 5 the ongoing subduction process to the east of the island.
- 6 The study area is predominately underlain by the Mariana limestone unit. This limestone unit is
- 7 composed mostly of finely to coarsely fragmented, commonly coralliferous, algal, and, in part,
- 8 clayey limestone (Cloud et al., 1956). The Mariana limestone typically is white to gray colored,
- 9 moderately to cavernously porous, and non-bedded to indistinctly bedded. In the coastal
- portions of the study area, the land surface is typically covered by recent alluvium derived from
- 11 erosion of the upland limestone areas.
- 12 Residents of the island of Saipan are almost entirely dependent on groundwater as a drinking
- water source. Historically, limited amounts of generally brackish water have been exploited by
- dug wells along the coastal portion of the watershed. Potable water is extracted from deep wells
- 15 (the Gualo Rai well field) located in the more inland portions of the watershed.
- 16 Groundwater in the western portion of Saipan occurs as an unconfined fresh to brackish water
- lens that overlies saltwater. The top of the aguifer is thus bounded by the water table surface.
- 18 Groundwater flows at a moderate gradient towards the ocean, becoming more brackish near the
- 19 ocean. The base of the aquifer in the inland portions of the watershed is the westward plunging
- 20 contact between volcanic basement and overlying coraline deposits. The depth to the volcanic
- basement in the coastal portions of the study area is unknown. The regional aquifer at the study
- area is made up of the coral and coral-derived material of the Marianas Formation. Due to the
- 23 high permeability of this limestone unit, the water levels within this aquifer fluctuate with ocean
- 24 tides (USGS, 2003).

- 25 The hydraulic conductivity of the Mariana Limestone, estimated from data collected at test wells
- 26 drilled into Marianas units in the Kagman area, ranges from 290 to 2,500 feet per day. The
- 27 calculated transmissivity values for the Mariana Limestone ranged from 7,600 to 62,000 square
- 28 feet (ft<sup>2</sup>) per day. The storage coefficient of the limestone, determined at one test well location
- in Kagman, is 0.06 to 0.11; the vertical conductivity at this location was estimated to be 0.1 feet
- 30 per day (Hoffman et al., 1998).

#### 2.2.5 Coral Reef and Lagoon Habitat

- 32 A healthy lagoon environment should have low abundances of seasonal macroalgae, and high
- 33 abundances of sand and coral, with some nearshore seagrass beds. Inner lagoon habitats have
- 34 the greatest amount of seasonal macroalgae due to their proximity to nutrient rich surface runoff
- 35 from land. Outer lagoon and back reef habitats have the highest water quality and water
- movement, and are the most biologically diverse areas as a result.
- 37 The Saipan Lagoon nearshore environment is generally composed of a sand and sand/silt/rubble
- 38 substrate covered by thick stands of seagrass and macroalgae with occasional coral colonies or
- 39 limestone outcrops. Heavy input of freshwater (groundwater and surface water runoff) into the
- 40 nearshore environment is conducive to dense beds of large bladed, tall (up to five feet) seagrass

- 1 (Enhalus acoroides) that are found in a 10 to 50 meter (m)-wide band along the shoreline.
- 2 Freshwater and entrained nutrients are known to enhance the growth of *Enhalus*, but excessive
- 3 nutrients are believed to promote abundant macro-algal growth that can have a negative impact
- 4 on corals and the function of the marine ecosystem (Houk and Camacho, 2010; Houk and Van
- 5 Woesik, 2008). Intermixed between stands of *Enhalus* and extending further out into the lagoon,
- often to the back reef, is the very common short seagrass *Halodule uninervis*, which covers 20 to
- 7 70% of the benthic substrate in the lagoon between the *Enhalus* beds and the coral reef.
- 8 Macroalgal abundance tends to increase from reef to shore with *Halimeda*, *Padina*, *Caulerpa*,
- 9 Laurencia, Acanthophora, and Dictyota included among the most common genera. In areas of
- high nutrient influx such as the northern end of the study area near Garapan, two types of rapidly
- growing, hair-like macroalgae, *Enteromorpha* and *Cladophora*, are dominant. The deep green
- 12 Enteromorpha and the paler Cladophora are considered nuisance algae by some because of their
- undesirable appearance and abundance along beaches and in the nearshore lagoon that are used
- 14 for tourist activities.
- 15 Corals in the inshore zone are very sparse and are characterized by scattered, small colonies of
- 16 Porites lutea and Pocillopora damicornis. Live coral cover is less than 1% overall, but some
- areas may support colonies of *Porites* and *Pocillopora* at densities of up to 5% cover.
- 18 Invertebrates conspicuous in the inshore zone include the common sea cucumber genera
- 19 Holothuria, Actinopyga, and Bohadschia, the large, blue starfish, Linckia laevigata, and the
- clam, Gafrarium pectinatum known locally as "Amsum". Lagoon fish resources include unicorn
- 21 fish (Nasinae), rabbitfish (Siganidae), mullet (Mugilidae), goatfish (Mullidae), snappers
- 22 (Lutjanidae), the emperor fish (Lethrinus harak), and silversides (Atherinidae). Juveniles of
- 23 many species may be found in the seagrass beds and local fisheries target certain groups.
- Occasional predatory species such as groupers, jacks and barracuda may also be present. Local
- 25 fishermen use these resources for both subsistence and sport. It is of common opinion that the
- 26 inshore fisheries are in decline, and information from the CNMI Department of Lands and
- Natural Resources (DLNR) would seem to support this contention (DLNR, 1998). Additionally,
- 28 fish surveys conducted by the University of Guam and DFW revealed a major decline in
- abundance of some of the major food fish groups between 1979 and 1996 in Saipan Lagoon
- 30 (Starmer et al., 2008). An island-wide market survey in 2009 documented the continued decline
- of nearshore fisheries (Houk, 2010). Specific habitat units in Saipan Lagoon have been identified
- and delineated by the MMT and are discussed in detail in Appendix C.4.

#### 2.3 STUDY AREA HISTORY

- 34 The Mariana Islands were discovered in 1521 by Ferdinand Magellan and were claimed for
- 35 Spain in 1565 by de Legaspi. By 1568, the Spaniards relocated all Chamorros living on the
- 36 Northern Mariana Islands (including Saipan) to villages on Guam in order to suppress
- 37 indigenous resistance to foreign rule. Carolinians from the outer islands of the Truk district were
- 38 the first Micronesians to repopulate Saipan in 1815 as a result of being displaced from their
- 39 home islands by a devastating typhoon. In 1899, Spain sold the Mariana Islands to the Germans,
- 40 whose primary contribution during their short occupation was the development of coconut
- 41 plantations for copra production. In 1914, the Mariana Islands were seized by a Japanese naval
- 42 fleet during the opening days of World War I (WWI). The League of Nations placed the islands
- 43 under Japanese mandate in 1920. The Japanese actively colonized and cultivated the Mariana

- 1 Islands during their tenure, triggering the first significant urban and agricultural growth on
- 2 Saipan. Roughly 32% of the land area on Saipan was planted with sugarcane by the 1930s, and
- 3 by 1937, a total of 42,000 Japanese were living on the Northern Mariana Islands. A
- 4 narrow-gauge railway was built around much of Saipan in order to transport harvested sugarcane
- 5 to the cane mill located in Chalan Kanoa. Garapan and the northern half of the study area served
- 6 as the commercial center on the island during the Japanese tenure. The Japanese heavily
- 7 fortified the island during WWII as a result of the island's strategic location in relation to the
- 8 Japanese mainland.
- 9 During WWII, US forces invaded Saipan on June 15, 1944, and successfully captured the island
- on July 9, 1944. The shoreline along the study area was heavily shelled during the invasion, as
- evidenced by the numerous live and dud ordnance that were encountered during construction of
- 12 the beach path. The military quickly embarked on numerous construction projects throughout
- 13 Saipan that required improving the existing transportation system on the island. Beach Road and
- 14 the Garapan area infrastructure were upgraded and further developed by the US Navy shortly
- after the war.
- 16 The US military government administered Saipan until 1947 when the US and United Nations
- 17 reached a trusteeship agreement that ultimately established the Trust Territory of the Pacific
- 18 Islands (TTPI), which included Saipan. The US Navy began administration of Saipan with the
- 19 establishment of the TTPI on July 18, 1947. Administration of the TTPI was transferred to the
- 20 US Department of the Interior on July 29, 1951, but was quickly transferred back to the US Navy
- 21 in November 1952. All the other Mariana Islands, except Rota, fell under the control of the US
- Navy shortly thereafter. Nearly a decade later, on May 7, 1962, the islands reverted back to
- 23 civilian control. On January 9, 1978, the Northern Mariana Islands were declared a
- 24 Commonwealth. On November 3, 1986, the Commonwealth was declared self-governing
- 25 (Farrell, 1991).
- Following a long period of relatively slow growth, Saipan underwent tremendous growth in the
- 27 1980s and early 1990s with the rise of the island's tourist and garment industries. This is
- 28 reflected in the explosive growth in the island's population during this period, from
- 29 approximately 15,000 in 1980 to over 62,000 in the year 2000 (US Census Bureau, 2000).

#### 30 2.4 HISTORICAL LAND USE AND POPULATION GROWTH

- 31 Since its establishment during the Spanish occupation in the 19th century, Garapan has
- 32 historically been the urban hub of Saipan and the Northern Mariana Islands. Japanese control of
- 33 Saipan in 1915 triggered the first significant modern population growth on the island and in
- 34 Garapan, which until then had remained relatively small, consisting predominantly of Caroline
- 35 islanders, Chamorros from Guam, and a few German settlers during the short German
- occupation (1899-1914). The Japanese occupation of Saipan during WWI brought thousands of
- 37 Japanese migrants, predominantly from Okinawa. Soon followed the development of intense
- 38 economic and agricultural activity on Saipan, with Garapan serving as the economic and social
- 39 center. By the 1930's, Garapan had evolved into a highly developed urban society, with urban
- 40 services capable of sustaining its population to Japanese standards. The city included retailers,
- 41 restaurants, bars, and factories from which products were exported as well as consumed locally.

- The population of Saipan grew steadily to approximately 30,000 by the end of WWII and the American invasion (Ono et al., 2002).
- 3 During the American invasion, Garapan was almost completely destroyed. Large areas of the town were completely leveled and replaced with cleared areas used for the construction of 4 5 military storage buildings and for military activities. The street patterns of Garapan that had 6 been established by the Japanese and the Germans were completely changed to fit American 7 military standards. The nearshore area between Beach Road and Middle Road was graded and 8 filled using coral limestone fill taken from nearby quarries to provide level surfaces for military 9 structures. It is estimated that approximately 75% of the coastal band within the study area 10 consists of "artificial fill", a predominant remnant of this post-war development. With the 11 departure of the Japanese and the end of the industrial and agricultural commerce, the population 12 decreased significantly after WWII, from 31,629 in 1944 to 4,898 in 1949. From 1949, the 13 population increased slowly but steadily, reaching approximately 20,000 in 1989. 14 introduction of garment factories during the 1990s, together with the rise of tourism, brought an 15 influx of laborers to Saipan, causing the population to explode to over 60,000 by 1999. At its 16 peak, there were 36 garment factories on Saipan which employed over 15,000 contract workers 17 mostly from Southeast Asian countries; however, there are currently no garment factories in 18 operation on the island with the last one having closed in 2009 (Goodridge, 2009). 19 population of Saipan as of the 2010 census is 53,883 (US Census Bureau, 2010). The closure of 20 garment factories on the island may have contributed to the slight decline in population.
- In an effort to document changes in land use within the study area over time, historical aerial photographs were collected, viewed, and compared. Aerial photographic coverage of this area is limited, but decent quality photographs from 1944, 1945, 1956, 1969, 1976, 2000, and 2009 were obtained and used for this analysis. Aerial photographs are included in Appendix D. Table 3 summarizes the changes in population growth for Saipan during the periods that each aerial photograph was taken.

6

7

8

15

**Table 3: Population and Urban Growth Summary** 

PHOTO DATE	RULING GOVERNMENT	APPROXIMATE POPULATION	*PERCENT URBAN COVERAGE OF STUDY AREA
1944	Japanese Trust Territory	31,129	15%
1945	United States Naval Military Government	No Data	71%
1956	Unites States Trust Territory	6,000	15%
1969	Unites States Trust Territory	10,000	17%
1976	Unites States Trust Territory	13,000	12%**
2000	Unites States Commonwealth	62,392	37%
2009	Unites States Commonwealth	53,883	43.5%

\*For this table "Study Area" includes the area bordered by the shoreline to the west, Middle Road to the east, and stretches from Garapan Fishing Dock to the north and Quartermaster Road to the South. The entire area is 260 acres. The percent urban coverage was calculated by using Autocad to calculate the areas of polygons drawn around urban areas on each of the historical aerial photographs within the area defined above. The percent urban coverage for the 2009 aerial photograph was calculated using ArcGIS.

\*\*The 1976 photo shows only a partial view of the study area; the percent urban coverage was calculated using the study area that is visible in the photograph.

- 9 Detailed descriptions of the aerial photographs, obtained for the time period extending from 1944
- 10 to 2009, are provided in the following sections. Major land-use changes observed in these
- photographs are summarized in Section 2.4.3. An emphasis on comparison of vegetative ground 11 12
  - cover pervades this historical analysis in an effort to link changes in exposed terrestrial areas
- 13 with changes in the lagoon environment. Interpretation of apparent changes within the lagoon
- 14 environment is discussed in further detail in Appendix C.3.

#### 2.4.1 Aerial Photographs

- 16 February 23, 1944. Black and White Aerial Photograph (Source: Bishop Museum, Honolulu,
- 17 Hawaii).
- 18 This photograph was taken by military reconnaissance during the Japanese occupation prior to
- 19 the American invasion. The population during this time was inflated due to the large number of
- 20 Japanese armed forces stationed on the island.
- 21 Visible in this photograph is the shoreline extending from just north of Garapan Fishing Dock to
- 22 the Susupe area to the south. Coverage extends inland approximately one-half mile, beyond the
- 23 present day Middle Road location. This photograph also includes offshore coverage of the
- 24 lagoon, nearly to the outer reef. The quality of this photograph of the study area and the
- 25 nearshore lagoon is good, with just a small portion of the lagoon obscured by cloud cover.

- 1 A dense band of development, extending from Garapan to the Gualo Rai area, is visible in this
- 2 photograph. The area appears to be highly urbanized, with an advanced street and block system
- 3 extending south from Garapan to the Gualo Rai area. Development in the area between the
- 4 shoreline and the approximate current location of Middle Road consists of very densely arranged
- 5 building structures and roads with little or no vegetative land covering. Further inland, bordering
- 6 this highly developed area, are areas that are cleared of trees and appear to be agricultural land.
- 7 Land located south of the development, in the areas of present day Quartermaster Road and
- 8 Susupe, consists mainly of agricultural land with little urban development.
- 9 Offshore coverage of the lagoon extends to just inside the outer reef. The lagoon is characterized
- 10 by a nearshore, light colored band that is assumed to be an area devoid of shallow water
- 11 vegetation or which is covered by sediment deposited from surface runoff. An adjacent dark
- 12 colored band that appears to be some kind of seagrass or algae extends from the nearshore
- sand/sediment band approximately one eighth-mile offshore. At this point, there appears to be
- striations in the lagoon bottom and a distinct contrast between the sea vegetation band, indicating
- an area of high energy or current that flows to the south.
- 16 May 9, 1945. Black and White Aerial Photograph (Source: University of Hawaii, Honolulu,
- 17 Hawaii).
- 18 This photograph was taken after the American invasion of Saipan, at which time large areas of
- 19 land were cleared and used for US military installations. The population of the island was still
- 20 impacted by the large transient military population.
- Visible in this photograph is the shoreline extending from just north of Garapan Fishing Dock to
- 22 the Susupe area to the south. Coverage extends approximately one and one-half miles inland.
- 23 This photograph also includes offshore coverage of the lagoon, to the outer reef on the lower half
- of the photograph and to just beyond the fishing dock in the upper portion of the photograph.
- 25 The quality of this photograph is good. The photograph was taken from an altitude of
- approximately 5,000 feet roughly eleven months after the American invasion of Saipan.
- 27 The study area appears significantly altered compared to the 1944 pre-invasion photograph. The
- 28 previously existing band of development, including structures and streets, has changed
- dramatically. Middle Road, Beach Road, and Quartermaster Road, as they appear today, are
- 30 visible and were apparently constructed by US forces shortly after the American occupation of
- 31 the island. The densely arranged, small building structures and street grid visible in the 1944
- 32 photograph are replaced by large tracts of cleared land covered by large military warehouses and
- 33 storage containers. The cleared land extends into the Gualo Rai area and to the inland side of
- 34 Middle Road to the south, for the entire extent of the study area.
- 35 This photograph shows a band of what is probably *Enhalus* seagrass nearest to shore. This black
- 36 band extends out to the deeper mid-lagoon region. The assumption is made that the *Enhalus*
- 37 seagrass region, similar to all other photographs, extends only a couple hundred meters off-shore.
- 38 The remaining portion of the black band in the 1945 image is probably *Halodule* seagrass or
- macroalgae stands. An additional bed of *Halodule* seagrass or macroalgae near the lighthouse in
- 40 the outer lagoon is shown in the image. This is significant because the deeper mid-lagoon region

- 1 is associated with stronger currents and tidal exchanges. These events would theoretically
- 2 exchange high nutrient lagoon waters before they reach the outer lagoon. The large stand of
- 3 seagrass present in the 1945 image suggests that nutrient rich groundwater may have been
- 4 affecting aquatic communities of the outer lagoon within the study area.
- 5 The beach/nearshore lagoon area is characterized by tracks in the lagoon floor that may be
- 6 remnant landing craft tracks from the invasion. There are several sediment deltas visible along
- 7 the shoreline, most likely a result of the large scale clearing for reconstruction. The dark band of
- 8 sea vegetation appears to be of equal width as the previous photograph and extends to the same
- 9 high energy-current band located inside of the reef.
- 10 December 9, 1956. Black and White Aerial Photograph (Source: University of Hawaii,
- 11 Honolulu, Hawaii).
- 12 This photograph was taken following the designation of Saipan as a Trust Territory of the United
- 13 States. The population and development reflect the relatively small population of permanent
- residents, with the military population having left with the closure of the last military installation
- 15 in 1950 (Spoehr, 2000).
- Visible in this photograph is the Saipan shoreline extending approximately from the Gualo Rai
- area to just south of Quartermaster Road. Coverage extends inland just beyond Middle Road.
- 18 This photograph also includes offshore coverage of the lagoon, to an extent of approximately
- 19 one-quarter mile. The quality of this photograph is good and it was taken from an altitude of
- approximately 1,500 feet.
- 21 The study area appears far less developed than in the invasion-era photographs. Areas that
- 22 previously appeared as exposed soil are now covered by vegetation. Vegetation appears to
- 23 consist predominantly of underbrush with sparse trees. Some of the warehouses, and cleared
- areas associated with the warehouses that were built in 1945, are still visible, but are overgrown
- with vegetation. Beach Road, Middle Road, and Quartermaster Road are visible.
- The lagoon appears to have changed, with a relatively small band of sea vegetation visible along
- 27 the shoreline. Sediment deltas are visible along the shoreline. The remaining portion of the
- 28 lagoon that is visible is sparsely vegetated and is characterized by a lighter albedo, which
- 29 probably reflects the presence of a relatively barren sandy lagoon floor. The high level of
- seagrass and macroalgae development is absent in this image. A band of *Enhalus* seagrass is still
- 31 visible in areas close to shore. The seagrass and macroalgae growth extending from shore to the
- 32 mid-lagoon region that was visible in the 1945 photograph is no longer visible. There is also no
- visible large development of seagrass or macroalgae in the outer lagoon that was previously
- present. The majority of the lagoon visible in the photograph consists of a barren sandy bottom,
- 35 which requires lower levels of nutrients in runoff water and groundwater to maintain. This is
- 36 consistent with the diminished level of onshore development present in the study area. Nonpoint
- 37 sources of pollution such as unpaved roads, and other sediment and nutrient sources within the
- 38 study area were not as widespread compared to the photograph taken in 1945.

- 1 January 29, 1969. Black and White Aerial Photograph (Source: University of Hawaii,
- 2 Honolulu, Hawaii).
- 3 This photograph was taken at a time of gradual increase in development/population of Saipan.
- 4 Visible in this photograph is the shoreline extending from Garapan to south of Quartermaster
- 5 Road. Coverage extends approximately one-half mile inland, beyond the present-day Middle
- 6 Road location. This photograph also includes offshore coverage of the lagoon, well beyond the
- 7 outer reef. The photograph was taken from an altitude of approximately 4,500 feet and is of
- 8 good quality.
- 9 The terrestrial landscape within the study area reflects little change from the 1956 photograph.
- 10 Development along the shoreline appears to be relatively unchanged other than advanced
- overgrowth of some of the WWII remnant structures.
- 12 The lagoon vegetation growth pattern appears to be unchanged, with sparse vegetation spots
- visible in a nearshore band, but little else extending to the outer reef. The visible sediment deltas
- also appear to be unchanged.
- 15 **February 23, 1976**. Black and White Aerial Photographs (Source: University of Hawaii,
- 16 Honolulu, Hawaii).
- 17 This photograph includes coverage of most of the study area, extending from Garapan Fishing
- 18 Dock to just south of Quartermaster Road. Onshore coverage is limited in these photographs,
- extending inland to Middle Road in the southern half of the study area, but extending only just
- beyond Beach Road in the northern half. This photograph also includes offshore coverage of the
- 21 lagoon, extending to just beyond the outer reef in the southern portion, and to just inside of the
- 22 outer reef in the northern half. The quality of this photograph is good, with slight cloud
- interference in the center of the area.
- 24 The continuation of gradual population/development growth is evident in this photograph.
- 25 Although coverage is limited, it is evident that there is more land development along Beach Road
- 26 than in the 1969 photograph. The density of urbanization is not at the level that it was in the
- 27 1940s, but it appears to be increasing. The lagoon appears unchanged from the 1969 photograph.
- April 25, 2000. Color Aerial Photograph (Source: R.M. Towill, Honolulu, Hawaii).
- 29 This photograph depicts present-day population/development levels. Saipan's status as a Trust
- 30 Territory of the United States, coupled with non-stringent labor laws, created the opportunity for
- 31 garment companies to produce clothing using cheap labor while still printing "Made in the USA"
- 32 on the labels. The rise of the garment industry in Saipan in the early 1990s brought a rapid
- 33 increase in population to the study area that has continued through the 1990s, raising the
- population from approximately 20,000 in 1989 to approximately 60,000 in 2000 (Farrell, 1991).
- 35 Visible in this photograph is the shoreline extending approximately from the Gualo Rai area to
- 36 just south of Quartermaster Road. Onshore coverage extends inland to just beyond Middle Road.
- 37 This photograph also includes offshore coverage of the lagoon, to an extent of approximately

- 1 one-quarter mile. The quality of this photograph is good and was taken from an altitude of
- 2 approximately 1,500 feet.
- 3 This photograph depicts present-day levels of development in the study area. The tract of land
- 4 between Beach and Middle Roads is significantly more developed than in the 1976 photograph.
- 5 Vegetation is still prevalent among many of the structures, unlike in the 1940s photographs.
- 6 Major terrestrial changes include the presence of a bike path constructed on the shoreline-side of
- 7 Beach Road and stretching the entire length of the study area, and the widening and pavement
- 8 improvement of Middle Road. Overall, the level of on-shore development closely resembles that
- 9 of the late Japanese era.
- 10 Nearshore sea vegetation consists of the relatively narrow, dark band of vegetation observed in
- 11 previous photographs. The remaining visible segment of the lagoon appears to have sparse
- 12 growth of sea vegetation. Several sediment deltas are visible at stormwater outfall locations.
- 13 The 2000 image shows the most resemblance to the 1945 image in terms of seagrass and
- macroalgae stands, and onshore development.
- 15 May 24, 2009. Color Aerial Photograph (Source: Google Earth 2009).
- 16 This photograph shows the most recent image of the study area from Garapan Fishing Dock to
- 17 just south of Quartermaster Road. Onshore coverage extends inland to just beyond Middle Road.
- 18 Although the southernmost portion of the study area is slightly obscured by cloud coverage, the
- 19 overall quality of the image is good.
- 20 As with the 2000 aerial photograph, this photograph depicts present-day levels of development in
- 21 the study area. Areas cleared of vegetation and paved areas have increased since 2000.
- 22 The narrow, dark band of nearshore sea vegetation and the relatively sparse growth of sea
- 23 vegetation in the remaining segment of the lagoon are consistent with the 2000 aerial
- 24 photograph, as well as with the 1945 aerial photograph. Sediment deltas are visible at the
- 25 stormwater outfall locations. The *Halodule* and macroalgae stand development in the outer
- lagoon near the lighthouse that was visible in the 1945 photograph is again visible in this
- 27 photograph. This appears to support the argument that increased onshore development (which
- leads to increased sediment/nutrient loads to the lagoon) results in altering the marine system by
- 29 stimulating *Halodule* and macroalgae growth.

#### 30 **2.4.2** Aerial Photograph Comparison

- In an effort to determine how land use has changed over time in the study area, the area of
- 32 developed land, including land cleared of vegetation (i.e., roads, buildings, and bare lots) visible
- 33 in each of the historic photographs was calculated. Coverage of the study area in each
- 34 photograph varies, and in some cases is incomplete; therefore, land areas calculated are general
- 35 estimates. The land area used for the comparison includes the area bordering the fishing dock to
- 36 the north, the lagoon shoreline to the west, Quartermaster Road to the south, and Middle Road to
- 37 the east. The purpose of this calculation is to compare sediment contributory areas within the
- 38 study area during recent history. Areas devoid of vegetation that are unpaved tend to contribute
- 39 greater amounts of runoff, and facilitate sediment transport than comparably sized areas that are

- 1 covered by natural vegetation. Cleared paved areas minimize sediment contribution, but
- 2 contribute excessive rainfall runoff to the shoreline. Middle Road and Quartermaster Road were
- 3 first constructed after the American occupation, and are thus not visible in the 1944 photograph.
- 4 Table 4 and Figure 3 depict the comparison of land use from 1944 to 2009.

Figure 3: Developed Land Within the Study Area

#### 2.4.3 Summary

During the Japanese occupation, Garapan was densely developed by structures and a street grid, and stretched into the northern portion of the study area. Dense development extended approximately to the southern end of the Guala Rai area, south of which consisted of land used primarily for agricultural purposes. The present day land use pattern and development of the

- study area stemmed from the American occupation of Saipan during WWII. This is evidenced
- 2 by the clearly visible Beach Road, Middle Road, and Quartermaster Road in the photograph
- 3 taken in 1945. The 1956 photograph depicts much of the WWII development to be overgrown
- 4 with vegetation, though the northern-most portion of the study area is not visible. Between the
- 5 1950s and present day, development of the study area has steadily increased, with a large
- 6 population growth spike during the 1990s from garment factory development, though the area of
- 7 land devoid of vegetation is still significantly less than what was present in 1945 during the
- 8 American occupation of Saipan.
- 9 Vegetation consisted only of the agricultural land in the 1944 photograph, with very little natural
- 10 vegetation present within the study area between present day Beach Road and Middle Road. The
- study area in 1945 was vastly changed with respect to building structures and roads, but the
- vegetation remained relatively unchanged, other than the advancement of overgrowth on land
- 13 formerly used for agriculture. The 1956 photograph shows the further advancement of natural
- 14 vegetation over the land formerly cleared during WWII. The vegetation growth pattern has
- 15 remained relatively unchanged to the present day, with the overgrowth primarily consisting of
- shrubs with a canopy of larger trees in some areas.
- 17 The shoreline, specifically the beach, is characterized by deltas of sediment deposits at entry
- 18 points of surface water runoff. These deltas are visible in all of the photographs, fluctuating
- minimally in size depending on the year. The beach appears to be at its widest in the 1945
- 20 photograph, while it seems to have remained relatively unchanged in the 1956, 1969, and 1976
- 21 photographs. There seems to be an increase in the size of the sediment deltas in the 2000
- 22 photograph, although there is a decrease in the overall width of the beach in comparison to the
- 23 1976 photograph. This is most likely the result of the construction of the beach path along the
- shoreline that acts as a barrier or armor, inhibiting the regeneration of the beach from eroded
- sediments. The increased size of the sediment deltas can be attributed to the increased sediment
- load entering the lagoon as a result of urbanization within the study area. Minimal changes are
- observed between the 2000 and 2009 aerial photographs, except for the increase in urbanized
- areas along Beach Road and Middle Road in the 2009 image.
- 29 The aerial photographs are of varying quality and scope, and some general trends can be deduced
- 30 from their review. Increasing urbanization within the watershed has led to the exposure of more
- 31 sediment, leaving the area susceptible to erosion and increasing the sediment load transported to
- 32 the lagoon during rainfall events. Lack of a stormwater control and/or treatment system has left
- 33 the lagoon susceptible to nutrient and contaminant-laden sediment, decreasing the overall quality
- of the lagoon environment.

#### 2.5 CURRENT LAND USE

- 36 The two major thoroughfares on Saipan, Beach Road and Middle Road, run through the study
- area, with the majority of urban development in the area concentrated along these two roads.
- 38 The watershed area inland of Middle Road is predominately covered by forest vegetation, with
- 39 the exception of the Gualo Rai community. The areas immediately adjacent to and in between
- 40 Beach Road and Middle Road are the currently most heavily developed areas within the study
- 41 area. These areas are where most of the PCAs within the study area are located (see Appendix

- 1 C.5). There is great potential that the entire land area between these two roads will become
- 2 heavily urbanized within the next decade due to its close proximity to the island's commercial
- 3 and governmental center in Garapan, and to meet the demands of a rapidly increasing island
- 4 population.

#### 5 2.6 WATER RESOURCES

- 6 Saipan has unique water issues that offer challenges to regulatory agencies such as the CNMI
- 7 DEQ and CRMO. Finite freshwater sources and impacts of urban development on surrounding
- 8 marine environments are of constant concern. Decreased water quality threatens marine
- 9 environments because coral reefs and other marine systems rely on good water quality for proper
- 10 function and prosperity. This section summarizes general water characteristics on Saipan
- according to the CNMI DEQ Integrated 305(b) and 303(d) Water Quality Assessment Report,
- 12 dated November, 2010 (DEQ, 2010).

#### 13 **2.6.1 Groundwater**

- 14 Two types of aquifers are dominant on Saipan, isolated limestone aquifers and the more
- prevalent basal aquifer, which serves as the predominant source of freshwater on the island. Due
- 16 to limited freshwater sources, the location and distribution of these aquifers is of extreme
- importance in the CNMI. Urban growth and an increase in population have led to several issues
- that threaten the freshwater aquifers. Increasing demand of freshwater has led to over-pumping
- of the basal lens aquifer, causing high chloride levels due to saltwater intrusion.
- 20 Although most occurrences of groundwater contamination in Saipan have not been linked with a
- 21 specific identifiable source, the highly suspected sources, in addition to saltwater intrusion,
- include the following:
- petroleum compounds from underground storage tanks;
  - pesticides, halogenated solvents, petroleum compounds, nitrate, metals, bacteria,
- protozoa, and viruses from disposal activities at landfills;
- nitrate, bacteria, protozoa, and viruses from septic tanks, as well as pipelines and sewer
- 27 lines; and

24

- halogenated solvents, petroleum compounds, and metals from small-scale manufacturing
- and repair shops.
- 30 These point and nonpoint source pollution due to heavy urbanization can threaten groundwater
- 31 sources through infiltration of the study area's highly permeable top soils.

#### **2.6.2 Surface Water**

- 33 The CNMI has designated two classes of water (AA and A) for marine uses. AA represents
- 34 high-quality waters that are considered to be in a "natural" and "pristine" state. The CNMI
- 35 Water Quality Standards state that "to the extent practicable, the wilderness character of such
- areas shall be protected," and does not permit any discharge of pollutants into class AA waters
- 37 (DEQ, 2002a). Class A waters have been designated in two parts of Saipan, and generally
- 38 represent a slightly lower quality of water in which some discharges may be permitted, for

- 1 example, the two sewage treatment plant outfalls on Saipan. Nevertheless, Class A waters must
- 2 support recreational use and the propagation of fish, shellfish, and wildlife. Strict water quality
- 3 standards have been set for the protection of these uses in Class A marine waters. Additionally,
- 4 further protection is afforded through the CNMI Anti-Degradation Policy, which is part of the
- 5 Water Quality Standards and protects existing uses and water quality in any waters, despite their
- 6 classification.
- 7 The majority of the coastal marine waters on Saipan are designated as Class AA, including the
- 8 study area. These waters should remain in their natural pristine state as closely as possible with
- 9 an absolute minimum of pollution or alteration of water quality from any human-related sources
- 10 or actions. The uses protected in these waters are the support and propagation of shellfish and
- other marine life, as well as the conservation of coral reefs and wilderness areas, oceanographic
- research, aesthetic enjoyment and compatible recreation inclusive of whole body contact (e.g.
- swimming and snorkeling), and related activities.
- Both point and nonpoint source pollution are responsible for lowering the quality of the CNMI's
- surface waters. Sewage out-falls, sewer collection overflows, sediment from unpaved roads and
- development, urban runoff, reverse osmosis discharges from hotel treatment systems, and
- 17 nutrients from agricultural areas and golf courses are the most significant contributors to the
- degradation of the CNMI's surface and marine water quality. Surface water quality is difficult to
- measure and properly assess due to the many interrelated variables that affect surface water,
- 20 including rainfall events, tidal fluxuations, and other atmospheric and oceanographic conditions.
- According to the MMT, in order to properly and accurately assess water quality, it is best to
- 22 couple both marine habitat health data with water quality measurements. Decreased water
- 23 quality threatens marine environments because coral reefs and other marine systems rely on good
- 24 water quality for proper function and prosperity. Further discussion of the effects of degraded
- water quality on Saipan Lagoon's ecosystem is provided in the next section.

## 3. PROBLEMS, GOALS, AND OBJECTIVES

- 2 The following sections describe the existing environmental issues in the study area and the need
- 3 for a restoration alternative that would meet the study objective of restoring the lagoon to a less
- 4 degraded, more natural condition. The importance of the lagoon ecosystem to the overall health
- 5 of the Saipan marine ecosystem is also discussed.

#### 3.1 EXISTING ENVIRONMENTAL ISSUES IN STUDY AREA

# 7 **3.1.1 Background**

1

- 8 Coral reefs are one of the most ecologically significant and diverse systems found within the
- 9 natural environment. Coral reefs provide habitats for 25% of all marine fish species although
- they cover less than 1% of the Earth's surface (Burke et al., 1998). Coral reefs serve as an
- integral part of Earth's ecosystem and also support a variety of human needs such as subsistence,
- 12 fisheries, tourism and recreation, shoreline protection, and even yield compounds that are used to
- develop new medicine. At least 500 million people depend on food, coastal protection, and
- 14 livelihoods provided by coral reefs (Wilkinson, 2004). Coral reefs are also of great cultural
- importance to many regions in the world.
- 16 Under the CWA (Section 404(b)(1), Part 230), coral reefs are considered "Special Aquatic Sites",
- and "they are geographic areas, large or small, possessing special ecological characteristics of
- 18 productivity, habitat, wildlife protection, or other important and easily disrupted ecological
- 19 values. These areas are generally recognized as significantly influencing or positively
- 20 contributing to the general overall environmental health or vitality of the entire ecosystem of a
- 21 region." The CWA also states that "degradation or destruction of special sites may represent an
- 22 irreversible loss of valuable aquatic resources."
- 23 In spite of their ecological, social, and economical value, coral reefs are in decline primarily
- 24 from global climate change, impacts from unsustainable fishing, and land-based pollution.
- 25 According to the Global Coral Reef Monitoring Network, the single largest coral reef monitoring
- 26 effort in the world, of all the reefs that is monitored worldwide, 27% has already been lost, and it
- 27 is predicted that another 32% could be lost in the next 20 to 30 years (Pockley, 2000). In
- addition, a report published by the World Resources Institute states that 58% of all reefs are at
- serious risk from human development. Both of these reports point to human activities as the
- major cause of decline in reefs (Weier, 2001).
- 31 This study focuses on one of the major causes of coral reef and ecosystem degradation;
- 32 land-based pollution that ultimately reaches the nearshore waters of Saipan Lagoon, which
- 33 ultimately causes alteration of the ecological system within the surrounding area. Some of the
- most diverse and economically significant coral reefs that support many forms of sea life are
- found in the CNMI. In Saipan, not only does the reef surrounding the island provide habitats for
- 36 numerous marine species, but also provides protection from typhoon damage and erosion,
- 37 supports fish species that are consumed regularly by local residents, and are used by local
- 38 residents and tourists for recreational purposes. Further degradation of the lagoon ecosystem due
- 39 to human activities will lead to ultimate destruction and irreversible loss of valuable aquatic

- 1 resources in Saipan. All components of the ecosystem rely on each other, and destruction of one
- 2 part of the system will cause the entire system to respond or to become altered. Implementing
- 3 management measures to reduce human impacts on the lagoon system is crucial in preserving a
- 4 healthy and natural balanced ecosystem within the study area as well as areas that are outside of
- 5 the study area.

## 6 3.1.2 Preservation Issues

- 7 Increasing population and urbanization have led to rapid development of Garapan, the largest
- 8 village on Saipan, and the study area just south of Garapan. The urbanization of the inland
- 9 watershed area that has occurred over the past twenty years has dramatically increased the
- amount of sediments and stormwater runoff discharged into Saipan Lagoon. The probable future
- increase in urbanization of this area would likely increase the volume of sediment, nutrients, and
- 12 contaminants entering the lagoon via rainfall runoff. During rainfall events, large sediment,
- 13 nutrient, and contaminant loads entering the lagoon have a deleterious impact on the water
- quality and aquatic ecosystems within the lagoon. Photographs showing the conditions of the
- 15 lagoon and surrounding areas during rain events are included in Appendix E.
- Results of the MMT's lagoon monitoring study and published literature (Houk and Camacho,
- 17 2010; Houk and Van Woesik, 2008) indicate that the inner lagoon habitats are affected by
- 18 increased nutrient load entering the lagoon via stormwater runoff within the study area. The
- 19 lagoon area that is within the study area receives drainage from the West Takpochau watershed,
- an area of dense commercial and residential development. Paved roads, asphalt parking lots, and
- 21 areas devoid of vegetation enable stormwater runoff to flow unimpeded to the lagoon,
- 22 transporting and depositing sediments, nutrients, and pollutants from the watershed to the
- 23 lagoon. As a result of the influx of additional nutrients, these nearshore habitats have higher
- 24 abundances of seasonal macroalgae growth and Enhalus seagrass compared to outer lagoon
- 25 habitats (Houk and Van Woesik, 2008). Components of the lagoon ecosystem are interrelated,
- 26 with the health of each depending upon the health and function of the other components.
- 27 Changes to a single component, in this case, increase in macroalgae due to the addition of
- 28 nutrients, affects the entire aquatic ecosystem and can totally change and eventually destroy the
- 29 naturally existing marine community. In general, an influx of too many nutrients will stimulate
- 30 growth of certain organisms within the ecosystem in the short term, and eutrophication over an
- 31 extended period of time will lead to overall degradation of the aquatic ecosystem by decreasing
- 32 the population diversity.
- 33 A healthy saltwater lagoon community in the region of this study should ideally be characterized
- by a band of nearshore *Enhalus* seagrass, adjoined by a predominantly sandy bottom with few
- 35 and sparse stands of macroalgae and *Halodule* seagrass. In the case of Saipan Lagoon,
- 36 sediment-laden stormwater runoff (associated with nonpoint source pollution) drains into the
- ocean, providing excess nutrients to the coral reef system. As a result, organisms that can utilize
- 38 these additional nutrients are quickly becoming dominant. In tropical marine systems, turf and
- macroalgae can uptake nutrients at a faster rate than corals or coralline algae (Littler and Littler,
- 40 1988). The result of continuous sediment-laden, nutrient-rich stormwater runoff entering the
- 41 lagoon is an increase in macroalgae cover to the detriment of seagrass and coral habitat. As
- 42 nutrient levels entering the lagoon have increased, there has been a shift from barren sand

- 1 regions to larger and denser macroalgae stands. In certain areas of the lagoon, particularly at the
- 2 northern end of the study area near Garapan, the continuous discharge of high nutrient waters
- 3 during storm events and from other point source discharges, such as runoff discharge or sewer
- 4 failures, has led to a shift from the once seagrass dominated system to a macroalgae dominated
- 5 community. The natural progression resulting from a continuous supply of high nutrient waters
- 6 entering the lagoon is the initial development of Halodule seagrass stands in sandy regions,
- 7 eventually to be overgrown by macroalgae (DEQ, 2002b). This macro-algal community has a
- 8 short life cycle and continuously changes from one species to the next. Marine communities
- 9 characterized predominantly by macroalgae also provide little refuge for juvenile fish when
- 10 compared to a healthy seagrass-dominated system.
- 11 Macroalgae are able to overgrow slower-growing coral and seagrasses, and eventually replace
- 12 them by creating a shaded environment that is not tolerated by these taxa. An increase in
- macroalgae also affects juvenile coral larvae that would normally settle and grow on the reefs, by
- reducing available area for settlement, resulting in a decrease in corals. Nutrients also promote
- turf and filamentous algal growth, which further reduces available area for coral settlement.
- 16 Fewer corals settling on the reefs leads to less available habitat for marine life to exist within the
- aguatic ecosystem, since corals provide habitat and refuge for the numerous species of fish and
- invertebrates that compose a healthy marine ecosystem.
- 19 In addition to altering the aquatic ecosystem due to increases in nutrient levels, increased
- sediment entering the lagoon can create the following problems:
- increase the turbidity of the water and block the sunlight from reaching corals and their associated photosynthetic symbionts;
- physically smother corals;
- prevent the recruitment and settlement of coral larvae;
- fine clay particles can clog the gills of smaller organisms;
  - larger particles such as sand and silt can scour organisms off the bottom and off of submerged rocks and coral;
  - deposited sediments can bury and smother sessile or sedentary bottom life, nests, and deposited eggs; and
- sediment deposit deltas continually shift with the influx of sediment during storm events, preventing reestablishment of undisturbed aquatic habitats.
- 32 Macroalgae communities are currently dominant in the lagoon at the northern end of the study
- 33 area, adjacent to the heavily urbanized Garapan. Continuation of the influx of sediment-laden
- runoff water, expedited by increasing development within the study area south of Garapan, will
- 35 likely lead to a shift to a macroalgae-dominated marine system within the southern portion of the
- 36 lagoon as well.

27

28

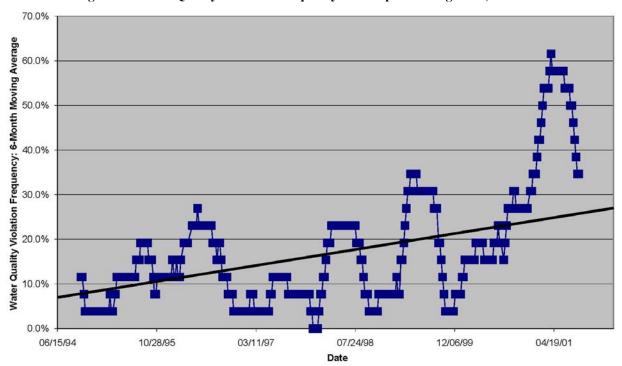

#### 3.1.3 Economic Issues

Deterioration of aquatic ecosystems and lagoon water quality is of concern not only for conservation issues, but also for economic reasons. The economy of Saipan is heavily reliant upon tourism with the sun, sandy beaches, spectacular reefs and marine life, and clean water being the primary attractions for tourists. Many hotels are located along the shoreline, with the beach and ocean providing the majority of tourist activities. Beach closures due to high levels of microbial contamination are becoming increasingly frequent along the west coast of Saipan (see Section 3.1.4). Additionally, the presence of nuisance macroalgae within the nearshore waters of Saipan has had deleterious impacts on the aesthetic value of the lagoon. Local fishermen who depend upon the reef for subsistence, as well as recreational and commercial fishing interests, are similarly concerned about the perceived degradation to the nearshore reef system. Further deterioration of the lagoon would be a great detriment to the tourist economy of Saipan and could cause irreparable harm to the economy of Saipan. The remainder of this section discusses specific factors that are contributing to the degradation of the lagoon ecosystem.

# 3.1.4 Water Quality

An interpretation of water quality data collected by DEQ from 1994 to 2002 indicates that there is a significant trend of increasing microbial (enterococci bacteria) contamination detections exceeding water quality standards. Figure 4 shows the increasing incidence of water quality violations at Garapan Fishing Dock located at the northern end of the study area.

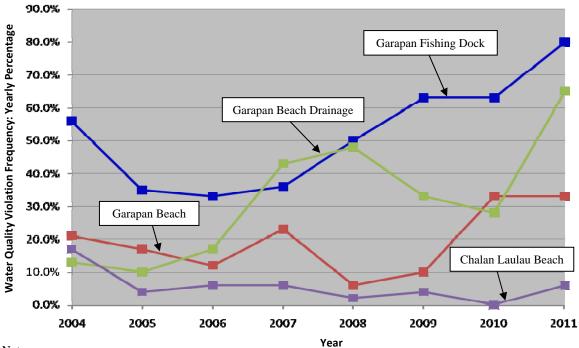

The increase in bacteriological contamination is a direct result of an increase in nonpoint source pollution associated with urbanization and population growth. Nonpoint source contamination occurs predominantly from surface runoff and sediments transported by runoff, solid and human waste disposal, and agricultural activities.

Water quality data from 38 fixed stations along Saipan's most commonly used west coast beaches collected during more recent years by the CNMI DEQ indicate that sampling sites within the West Takpochau (Central) Watershed continue to consistently experience a significant number of water quality violations, leading to multiple "impaired" (violation frequency exceeds 10%) or "significantly impaired" (violation frequency exceeds 25%) listings (DEQ, 2010). Beach advisories notifying the public that the beach waters within 300 feet of the sampling point are not safe for swimming are triggered when either the single sample maximum (SSM) or geometric mean (GM) for the most recent four sampling events exceeds the CNMI water quality criteria. Figure 5 shows the yearly percentage of water quality violations from 2004 to 2011 at four of the DEQ sampling stations that fall within the study area. Three stations (Garapan Fishing Dock, Garapan Beach, and Garapan Beach Drainage) occur at the northern end of the study area, whereas Chalan Laulau Beach occurs within the southern portion of the study area.

Notes:

1. Contaminant: Enterococci

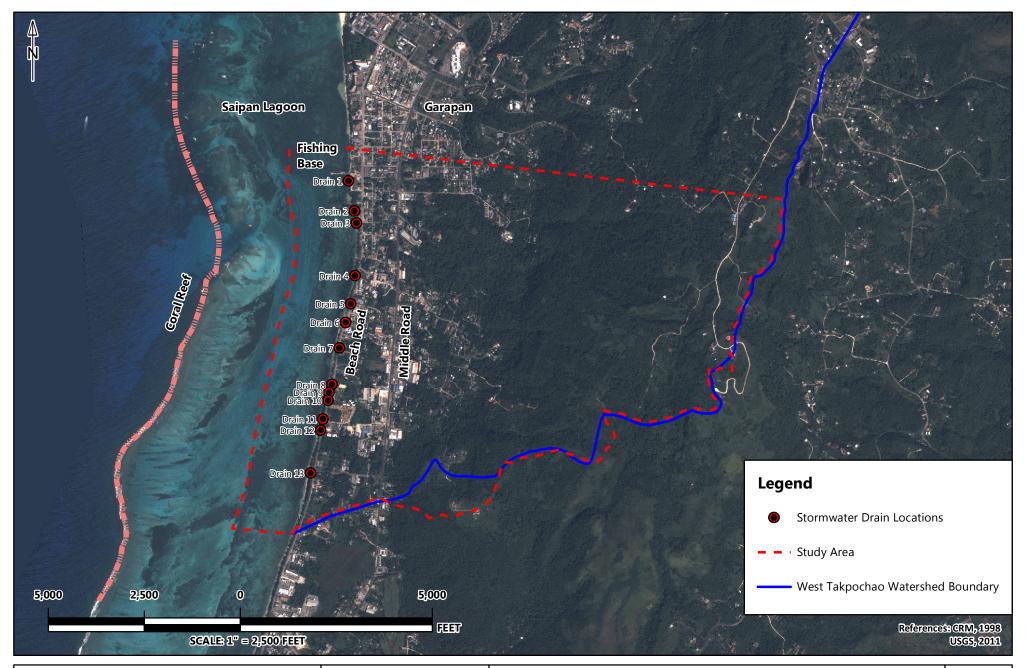

2. Violation frequencies are based on the number of samples (either the SSM or GM where sampling data exists for four previous sampling events) that exceeded the CNMI water quality criteria.

Water quality violation frequencies over the past eight years at the three stations located at the northern end of the study area show an overall increasing trend, which is likely due to the more

- densely populated and urbanized areas within the northern part of the study area. On the other
- 2 hand, water quality violations at Chalan Laulau Beach in the West Takpochao (South)
- 3 Watershed, which is less populated and urbanized, peaked in 2004 at 17%, and have
- 4 subsequently decreased to 0-6% in recent years. In fact, the CNMI has proposed to delist the
- 5 West Takpochao (South) segment from the impaired listing based on improvements in water
- 6 quality relative to enterococci contamination. However, the impaired listing of the West
- 7 Takpochao (South) segment (total maximum daily load (TMDL) required, medium priority) is
- 8 also related to low dissolved oxygen (DO) contents, bio-specific criteria, and the frequent
- 9 occurrence of orthophosphates from sanitary sewer overflows (SSOs), urban runoff, and
- 10 sedimentation.
- 11 The West Takpochau (Central) Watershed is also listed as impaired, TMDL required, and given
- 12 a high priority designation by the CNMI. This impaired listing is specific to dangers to aquatic
- 13 life, fish consumption, and recreation as a result of enterococci, mercury, DO, biocriteria, and
- orthophosphate contamination from sanitary SSOs, urban runoff, and sedimentation (DEQ,
- 15 2010). Water quality data collected within the study area, as well as the impaired listings of the
- watershed areas, indicate that anthropogenic degradation of the water quality within the lagoon
- remains an issue and continued close monitoring of the lagoon water quality is necessary.
- 18 Improved water quality will lead to a more sustainable environment for the marine species in the
- 19 lagoon as well as decreased seasonal macroalgae growth which is stimulated by the influx of
- 20 nutrient-rich water. Less macroalgae growth within the lagoon will in turn allow slower-growing
- 21 coral and seagrass to become more dominant in the area providing habitats for many species of
- fish and invertebrates.

#### 3.1.5 Flooding

- 24 At present, there are 13 storm drainage outlets within the study area that drain into Saipan
- Lagoon (Figure 6). The drains were originally installed during construction of Beach Road in
- 26 the early 1980s. Headwalls for the drain outlets were constructed when the beach walk (bike
- path) was built in the mid-1990's. These storm drains collect stormwater from the immediate
- vicinity of Beach Road (i.e. runoff from Beach Road and properties adjacent to the road. A
- 29 typical storm drain consists of a grated catch basin on the inland side of Beach Road, followed
- 30 by 30-inch diameter reinforced concrete pipes (RCPs) that run beneath Beach Road and convey
- 31 the stormwater from the catch basin to the lagoon. Drainage outlets consist of a single 30-inch
- 32 diameter RCP or multiple 30-inch RCPs.
- 33 Middle Road parallels Beach Road about a half-mile inland and is similarly drained by three
- 34 individual storm drains. The design of the drains is similar to that of Beach Road with catch
- basins on the inland side of the road and outlets on the seaward side of the road. The contributory
- 36 flow from the upland areas of Middle Road consists of overland flow and patchwork drainage
- 37 swales, but no unified drainage system. The drains along Middle Road discharge to the
- 38 properties between Beach Road and Middle Road. However, there is no connection between the
- 39 storm drains on the upper road and those on the lower road. There does not appear to be any
- 40 drainage easement through this area. Since the topography between Middle Road and Beach
- Road is relatively flat, runoff tends to pond in the area during moderate to heavy rainfall, before
- 42 making its way to the lagoon. Only a small fraction of the runoff from properties inland of

PROJECT NO.: 1057	ECOSYSTEM RESTORATION REPORT	
DATE: SEPTEMBER 20, 2012	SAIPAN LAGOON AQUATIC ECOSYSTEM RESTORATION STUDY	FIGURE
DRAWN BY: CB	STORM DRAIN OUTLETS WITHIN THE STUDY AREA	6
REVIEWED BY: MA	SAIPAN, CNMI	

1 Middle Road reach the storm drains at Beach Road during small intensity rainstorms, with the 2 majority of the runoff infiltrating into the highly permeable limestone. Depending on the 3 severity of the rainfall event, heavy flooding of the down-slope properties and roads occurs. During moderate to heavy rainfall events, both Middle and Beach Roads become severely 4 5 flooded. Without a system to properly divert and capture stormwater runoff, and release in a 6 more controlled manner, untreated land-based contaminant, nutrient, and sediment laden runoff 7 water is more likely to overflow and enter nearshore waters within the study area during large 8 rain events. With a proper system to capture stormwater runoff, the amount of contaminant, 9 nutrient, and sediment entering the lagoon will be more controlled, leading to a better 10 environment for proper ecosystem function.

#### 3.1.6 Runoff and Sedimentation

11

12 Increased sediment, nutrient, and contaminant loads entering the lagoon can be generally 13 attributed to several factors, including: the lack of comprehensive land management planning 14 and zoning practices, the absence of an adequate stormwater collection and conveyance system, 15 and the removal of vegetation that serves to detain and filter sediments naturally. Prior to urban development of the study area, the majority of sediment and stormwater runoff was trapped by 16 17 the natural vegetation present along the coastal plain before reaching the lagoon. Many of the 18 roads and building lots between Beach and Middle Roads and upslope of Middle Road are 19 unpaved, exposing loose sediment to surface water runoff during rain events. Because of the 20 lack of an adequate stormwater collection, conveyance, and treatment system, sediment is 21 directly transported from these exposed areas to the lagoon. During heavy rain events, surface 22 runoff water flows unimpeded down roads and through parking lots to the lagoon.

23 Sediment transported from the watershed to the lagoon contains high levels of nutrients as well 24 as contaminants. Sediment-laden runoff waters transport surficial contaminants from upslope 25 surfaces and deposits them into the lagoon. Contaminants vary depending upon activities that take place within the watershed (e.g., construction, agricultural, or mechanical). The resulting 26 27 increased levels of runoff and sedimentation to the lagoon overload the ability of the natural 28 seagrass and coral communities to cope with these pollutants and can damage these delicate 29 ecosystems. Damage to coral reef ecosystems can result from direct sedimentation onto coral 30 polyps or from increased nutrient concentrations that may lead to overgrowth by algal species. In addition, pollutants that are carried by the stormwater can cause damage to the reefs by 31 32 blocking coral fertilization during spawning events, some of which occur only twice per year. 33 Finally, a large influx of freshwater runoff into the shallow lagoon changes the salinity of the 34 water, potentially outside the narrow range required to sustain healthy corals.

A shift in reef species towards more nutrient tolerant and less diverse communities as a result of increased levels of runoff and sedimentation will also lead to changes in the fish populations inhabiting the reef. In addition, less diverse communities of coral are more susceptible to damage during natural disasters such as typhoons. In order to prevent further irreversible damage to the nearshore ecosystem in Saipan Lagoon, it is critical to implement management measures to control or reduce the amount of sediment, nutrient, and contaminant loads entering the lagoon.

# 3.1.7 Contamination of the Lagoon

21

22

23

24

25

26

27

28

35

- 2 At present, the homes and businesses within the study area are not connected to a municipal
- 3 sewer system and use septic systems for disposal of wastewater. No records were available
- 4 describing the number and location of septic systems in the area. Local regulatory officials
- 5 suggested that some gray water disposal is discharged directly to the surface without benefit of a
- 6 septic system or leach field. It is believed that septic system failures probably contribute a
- 7 significant amount of nutrients to the nearshore waters within the study area. The CWA Section
- 8 319 Nonpoint Source Grant Program administered by the DEO Nonpoint Source Pollution
- 9 Control Program is currently funding an on-going inventory and inspection of septic systems
- throughout Saipan (DEQ, 2010).
- 11 SSOs have been reported for the existing wastewater collection system. However, there are no
- 12 records that detail the frequency, location, quantity, cause, or affected area. The only
- information available is a trouble call log. There have been reports that some overflows have
- 14 caused wastewater to be discharged into the nearshore marine environment. According to local
- personnel familiar with the system, the major causes for SSOs have been reported to be:
  - Failure of lift station pumps due to clogging of the impellers.
    - Capacity of the collection system exceeded during storm events. During storm events, collection systems occasionally receive excessive flow and infiltration causing them to backup and overflow.
    - Large portions of the existing collection systems in the Chalan Kanoa/Kobler area and in the Garapan area were constructed in the early 1970s. The original sewers were constructed using vitrified clay pipe. The age of the sewer coupled with the pipe material may be conducive to leaks.
    - The sewers are located in areas that have a shallow groundwater table, further increasing the possibility of contamination.
      - Localized flooding during storm events may lead to inflow at discrete points within the collection system (e.g., manholes or lift station wet wells), and subsequent overloading of the collection systems.
- 29 As discussed in earlier sections, nutrient enrichment leads to overgrowth of macroalgal species
- 30 that can uptake nutrients faster than corals, coralline algae, or seagrass communities, eventually
- 31 outgrowing these species. Fewer seagrass and coral communities mean that there will be less
- 32 available habitat and refuge for many species of fish and invertebrates to exist. In order to
- restore and sustain a healthy lagoon environment, measures must be taken to control the amount
- of nutrients entering Saipan Lagoon.

# 3.2 PROBLEM AND OPPORTUNITY STATEMENTS

- 36 Sedimentation and increased nutrient load is recognized as one of the most significant problems
- facing Saipan Lagoon and is a direct result of urban development that has taken place within the
- 38 West Takpochau watershed. The following items provide a summary of the main problems
- 39 identified within the study area:

- Continued input of nutrient-rich stormwater runoff into the lagoon has led to a shift from the once seagrass dominated system to a macroalgae dominated community within the inner lagoon habitats, which can be detrimental for the development of slower-growing coral and seagrass.
- Increased sediment load entering the lagoon via stormwater runoff can hinder the development and growth of corals and other organisms by increasing the water turbidity or by physically smothering them and their habitats.
- Increased frequencies of microbial contamination detections exceeding water quality standards as a direct result of increase in nonpoint source pollution associated with urbanization and population growth has contributed to a shift to a macroalgae dominated system in the nearshore waters.
- Increasingly frequent beach closures due to high levels of microbial contamination and the presence of nuisance macroalgae within the nearshore waters have had deleterious impacts on the recreational use as well as the aesthetic and economic value of the lagoon.
- Decline in abundance of nearshore fish species is not only a concern from an ecological standpoint but also a concern for economical reasons for local fishermen who depend on the resources for subsistence.

#### 3.3 FORECASTED WITHOUT-PROJECT CONDITIONS

- Future outcomes without implementation of preventive measures to address the problems identified in the study area are as follows:
  - Continuous supply of nutrient-rich waters to the lagoon will continue to enhance the growth of macroalgae within the nearshore area, especially in the northern end of the study area adjacent to the heavily urbanized Garapan where macroalgae communities are currently dominant.
  - The macroalgae community that is currently dominant in the northern end of the study area will eventually replace the slower growing coral and sea grasses, which will lead to less or no available habitat for marine life to exist within that area of the lagoon.
  - Alteration of one area of the lagoon, in this case the northern part of the study area, is likely to negatively impact and cause imbalance within the ecosystem of the remaining portions of the lagoon.
  - Continuous supply of nutrient-rich waters to the lagoon will likely lead to a shift to a
    macroalgae-dominated marine system within the southern portion of the study area as
    well.
    - Continued input of sediment into the lagoon via stormwater runoff will hinder the development and growth of corals and other organisms by increasing the water turbidity or by physically smothering them and their habitats, which will lead to a decrease in the diversity of marine species within the lagoon ecosystem.

- Continued enhancement of macroalgae growth within the study area will lead to eventual depletion of valuable aquatic resources including the coral reef and the organisms that it supports.
  - Microbial contamination associated with nonpoint source pollution will further enhance the growth of macroalgae as well as result in increased frequencies of beach closures within the study area.
  - Increasingly frequent beach closures due to high levels of microbial contamination and the presence of nuisance macroalgae within the nearshore waters will have negative impacts on the tourism industry in Saipan as many hotels are located along the shoreline within the study area.
  - The decline in abundance of nearshore fish species as a result of ecosystem degradation within the study area will have a negative impact on the local economy as many local fishermen depend on the resources within the study area for subsistence and because marine life is one of the major tourist attractions in Saipan.

#### 15 3.4 STUDY OBJECTIVES

- 16 The objective of this study is to recommend an environmentally sensitive and economically
- 17 feasible restoration alternative that would best restore the degraded aquatic ecosystem structure,
- 18 function, and dynamic processes to a less degraded and more natural condition. The objectives
- 19 of the restoration alternative are to:
  - Reduce the abundance and frequency of occurrence of fast growth nuisance macroalage within the study area.
- 22 • Decrease the amount of sediment and nutrients that enter the lagoon.
- 23 • Decrease the concentration of microbial contamination in nearshore waters of the lagoon.
- 24 A detailed description of the quantitative goals of these objectives is further discussed in Section
- 25 5 of this report. Achievement of these objective would improve the lagoon ecosystem in the
- 26 following ways:

1

2

3

4

5

6

7

8

9

10

11

12 13

14

20

21

- 27 • reduce the amount of nutrients entering the lagoon, thus enabling natural seagrasses, 28 corals, and aquatic life to regenerate in areas currently dominated by macroalgae, 29 characteristic of a high nutrient environment;
- 30 reclaim nearshore areas of the lagoon ecosystem that are currently inundated with sediment:
- 32 • regain diversity within the aquatic ecosystem; and
- 33 improve lagoon water quality to a state conducive to coral reef ecosystem restoration.
- 34 Reduction of the sediment and nutrient load transported to the lagoon would significantly
- 35 improve the overall function of the aquatic ecosystem. Restoration of the lagoon ecosystem
- would also benefit the local tourist economy, the fishery, and the overall development of Saipan. 36

3

4

5

6 7

8

9

- 1 Constraints that may restrict achievement of the study objectives include the following:
  - Factors that are not directly linked with stormwater runoff that the restoration alternative intends to address, such as groundwater or other drainages outside of the study area, may have influence on the outcome of the project.
    - Limited knowledge on the specific sources of nutrient and sediment loads that enter the lagoon as well as runoff processes within the watershed may restrict the ability of the restoration alternative to address these issues in the study area.
    - Natural disasters such as large hurricanes or tsunamis during implementation of the management measure may pose limitation to assess the outcome of the project.
- Alternative plans will need to take these constraints into consideration in order to reach the planned study objectives and to achieve the desired outcomes.

#### 4. BASELINE MONITORING RESULTS

2 Review of previous biological and environmental studies conducted on Saipan during the Phase I

3 portion of this study identified a number of additional studies required to adequately establish

4 baseline environmental conditions within Saipan Lagoon. The results of these baseline studies

5 will be used to aid in the development of remedial measures within the study area and will

6 facilitate evaluation of the effectiveness of these measures in the future. In addition, data derived

from field studies was used to assist in identification of deleterious impacts of contaminant

8 sources entering the lagoon. The data generated by these studies will be combined with the

existing site data and utilized to refine the design of future remedial measures. The CNMI DEQ

and CRMO personnel were instrumental in many of these studies, assisting with research,

11 laboratory analyses, and field activities.

39

## 4.1 STORMWATER QUALITY INVESTIGATION

13 Stormwater runoff samples were collected between February and December 2002 from four

storm drains located along the shoreline within the study area, one storm drain located south of

15 the study area, and two storm drains located north of the study area, and analyzed for priority

pollutant metals. The stormwater runoff sample results were compared against the EPA national

17 recommended water quality standards for priority pollutants (EPA, 2009), chronic and acute

toxicity values for the freshwater aquatic life criteria. Cadmium, copper, lead, nickel, selenium,

and zinc were detected at a concentration exceeding the acute or chronic toxicity standards in at

20 least one of the samples collected.

21 Some metal species were detected at elevated concentrations during times of high stormwater

discharge, which provides some evidence for anthropogenic sources of these metal species

23 washing into the lagoon via stormwater runoff during large rainfall events. However, runoff

sample exceedances occurred during both the dry and wet season, and the results were not

consistent enough to conclude that more metals are carried into the lagoon during larger rainfall

events. Rather, the results of this 2002 study likely suggest that the amount of metals that are

27 carried into the lagoon via stormwater runoff are more dependent on the source of contamination

28 (e.g., from pervious vs. impervious surfaces) and the relative timing of the rain event.

29 Stormwater runoff during early season rains or after a prolonged dry period usually contain the

30 highest pollutant content due to the amount of time that has allowed pollutants to be deposited

and accumulate on impervious surfaces. Pollutants from pervious surfaces on the other hand

32 may be found at a constant rate regardless of the timing of the rain event. Additional

33 investigation and more frequent stormwater quality monitoring would be required to determine

34 the sources of metal pollutants and assess their timing of release into the lagoon relative to

35 precipitation and runoff totals. Since the current study proposes a solution that will capture and

36 retain contaminated stormwater regardless of the source of metal pollutants, additional study is

37 considered outside the scope of this study. A detailed description of the 2002 investigation

results as well as the laboratory analytical reports are included in Appendix C.1.

#### 4.2 LAGOON SEDIMENT PHYSICAL AND CHEMICAL PARAMETERS

40 As part of an effort to characterize the general distribution and abundance of pollutants in

41 sediments in the study area, a total of 18 surface sediment samples were collected from the

- lagoon bottom in September 2002. Samples were collected from six transects extending from
- 2 nearshore to the outer lagoon, stretching the entire length of the study area. The starting point
- 3 for each transect was established at five storm drains located along the shoreline of the study area
- 4 as well as a wetland location at the southern end of the study area.
- 5 Each transect included a sample location within the nearshore *Enhalus* beds, within the nearshore
- 6 Halodule band, and within offshore Enhalus beds located beyond the channel. These sampling
- 7 locations were estimated to be at 250 m, 500 m, and 1,000 m from shore. Each sediment sample
- 8 was analyzed for priority pollutant metals, polychlorinated biphenyls (PCBs), and polycyclic
- 9 aromatic hydrocarbons (PAHs), as well as specific PCB congeners known to be found north of
- the study area in the Tanapag area during the Water and Environmental Research Institute of the
- 11 Western Pacific (WERI) study.
- 12 As a non-regulatory comparison, analytical results of sediment samples were compared to the
- 13 EPA regional screening levels (RSLs) for residential soil (EPA, 2012). Overall metals
- 14 concentrations detected in lagoon sediment were low, but analytical results indicate that in
- 15 general, sediment collected from the nearshore contained slightly higher concentrations of metals
- 16 than those samples collected from mid- to off-shore locations. Concentrations of arsenic
- 17 exceeded the EPA RSL for residential soil in some or all of the locations for all six transects.
- 18 Concentrations of arsenic detected in samples ranged from 5.1 to 12 milligrams per kilogram
- 19 (mg/kg), compared to the residential RSL of 0.39 mg/kg.
- 20 PCBs, PAHs, and PCB congeners were not detected in any of the samples above the laboratory
- 21 reporting limits. All laboratory reporting limits were below the EPA RSLs except for
- benzo(a)anthracene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene.
- 23 More recent data characterizing the sediment composition of Saipan Lagoon are available from a
- 24 study conducted by Denton and Starmer (2009) in which sediment samples for heavy metals
- analysis were collected from 16 of 22 coastal stormwater discharge points that currently exist
- along the southern half of the lagoon. Surface sediments were collected at offshore locations at 0
- 27 m, 10 m, 25 m, 50 m, 100 m, and 250 m from shore along transect lines perpendicular to the
- discharge points. Samples were also collected from 500 m and 1,000 m offshore where possible.
- 29 Geometric means were calculated at each distance and the minimum and maximum
- 30 concentrations were determined.
- 31 Metals concentrations found in surface sediment samples collected in 2009 were all below the
- 32 EPA RSL, and were similar to those found in sediment samples collected in 2002. The 2009
- data collection found the highest levels of metals in sediment samples close to shore, as opposed
- 34 to those collected further offshore. This is in agreement with findings from the 2002 data
- 35 collection and appears to support the theory that urban runoff is one of the major contributing
- 36 sources for metal contamination in the lagoon sediment. A detailed discussion of the sediment
- sample results as well as the laboratory analytical reports are included in Appendix C.2.

20

21

# 4.3 HISTORICAL ASSESSMENT OF THE LAGOON FROM AERIAL PHOTOGRAPHS

- 3 A historical assessment of the lagoon environment was completed simultaneously with the
- 4 historical assessment of the land area. A detailed description and visual analysis of the aerial
- 5 photographs are included in Section 2.4. DEQ marine biology staff members were instrumental
- 6 in the interpretation of changes in the lagoon environment apparent in the aerial photographs.
- 7 Historic aerial photograph comparisons indicate that the nearshore lagoon ecosystem has shifted
- 8 from a healthy seagrass and sandy-bottom community to a less healthy, macroalgae dominated
- 9 community in response to heavy urbanization and development within the watershed both
- 10 currently and in the past. A detailed assessment of the lagoon environmental change observed
- from aerial photographs of the study area is included in Appendix C.3.

## 12 4.4 INSHORE LAGOON SEAGRASS AND ASSOCIATED FAUNA SURVEY

- 13 The MMT Saipan Lagoon monitoring effort has completed an inventory of the lagoon, including
- 14 the study area. Results of the initial assessment efforts in the study area indicate that the inner
- 15 lagoon habitats are affected by increased nutrients associated with stormwater from the West
- 16 Takpochau watershed reaching the drainages and shores in this region, and entering the lagoon.
- 17 These habitats have high abundances of seasonal macroalgae growth when compared to outer
- 18 lagoon habitats. The MMT has designated 18 habitat classifications within the lagoon. Detailed
- descriptions of the habitats that exist within the study area are included in Appendix C.4.

# 4.5 INVENTORY OF POTENTIALLY CONTAMINATING ACTIVITIES IN WATERSHED

- 22 An integral part of this aquatic ecosystem restoration study was to identify land-based sources of
- pollution that could potentially contribute nutrients, sediments, or contaminants to the lagoon.
- 24 PCAs within the study area were inventoried and subjected to a susceptibility analysis. Fifty
- four (54) sites were identified during the PCA inventory. The number and category of PCAs
- 26 found within the study area were used to quantify the environmental output that would result
- from implementing the restoration alternatives. A detailed discussion and inventory of the PCAs
- within the study area are included in Appendix C.5.

#### 29 4.6 GROUNDWATER INVESTIGATION

- 30 Nearshore groundwater samples were collected along the entire length of the study area and
- 31 beyond in March, June, and August, 2002, in an effort to determine the impact of on-shore
- 32 surface contaminants on the lagoon via groundwater infiltration. The 2002 analytical results
- indicate that there are elevated nitrate levels in nearshore groundwater infiltrating to the lagoon.
- 34 Nitrate levels of nearshore coastal marine waters may be affected by activities within the
- 35 watershed.
- 36 Although semi-annual groundwater monitoring, including monitoring for nitrate indicators, has
- 37 been required by the DEQ for many years, more recent groundwater data collected within the
- 38 study area are not available due to the lack of a comprehensive groundwater management plan
- 39 that includes methods for analyzing the collected samples and actions to be taken based on the

- data collected (DEQ, 2010). The nearshore groundwater nitrate results from 2002 are included
- 2 in Appendix C.6.

#### 3 4.7 HYDROLOGIC STUDY OF RUNOFF PROCESSES IN THE WATERSHED

## 4 4.7.1 Rainfall and Runoff Data Collection

- 5 In order to help determine general comprehensive hydrologic processes within the study area,
- 6 rainfall and runoff data were collected in 2002 from rain gauges, transducers, and by manual
- 7 measurements within the study area. Stormwater peak flow rates at nearshore locations were
- 8 found to range from 12 gallons per minute (gpm) to 1,000 gpm at individual discharge locations.
- 9 Although no additional rainfall data has been collected at the study area since 2002, the 2002
- data indicates that large volumes of runoff from the steep upper/inland portion of the watershed
- 11 flows down onto Beach Road and enters the lagoon via surface sheet flow during large rain
- events. Rainfall and runoff data collected in 2002 as well as a detailed discussion of the results
- are included in Appendix C.7.

## 14 4.7.2 Sediment Delta Surveys

- 15 In an effort to quantify the sediment load entering the lagoon via stormwater runoff, three
- sediment deltas within the study area were surveyed five times from 2001 to 2002, during both
- 17 the wet and dry seasons. The approximate volumes of the sediment deltas were measured and
- 18 compared against the corresponding monthly rainfall data during each monitoring event. The
- 19 change in sediment delta volume throughout the study interval varied among the survey
- 20 locations. The total volume of sediment lost from the three deltas during the study interval was
- 478 cubic yards. The volume of sediment lost was most likely washed into the lagoon during the
- 22 two-month period. The results of the sediment delta surveys are included in Appendix C.7.

#### 23 4.8 LAGOON WATER QUALITY INVESTIGATION

- 24 In order to obtain general lagoon water quality data, lagoon water samples were collected by
- DEQ personnel from February 2002 to February 2003. Samples were collected in nearshore
- 26 waters adjacent to three storm drains located within the study area and one storm drain located
- 27 immediately south of the study area. Samples were analyzed for microbiological and chemical
- 28 parameters by the DEQ Environmental Surveillance Laboratory. The analytical results were
- compared against the CNMI water quality criteria for Class AA marine waters (DEQ, 2010).
- 30 During the 2002-2003 sampling period, water quality standard exceedances were regularly
- 31 observed for instantaneous enterococci measurements, DO, turbidity, hydrogen activity (pH),
- 32 nitrate, and orthophosphate, although strong correlations among the measured parameters were
- 33 not noted. Average values of the water quality sample results for the 2002-2003 sampling period
- during the wet season (July through November) and dry season (December through June) were
- calculated for all parameters except fecal coliform. Enterococci values were consistently higher
- at all four sample locations during the wet season than during the dry season, as was turbidity at
- three sample locations. Salinity was consistently higher during dry season sampling events at all
- four sample locations, as were DO and chloride. These patterns fit the general presumption that
- 39 nearshore lagoon waters are affected by an increased volume of stormwater runoff during the
- 40 rainy season, leading to an increase in turbidity and microbial contamination. During the dry

- season, less freshwater runoff is experienced, leading to higher salinities and chlorides, and
- 2 lower turbidity and less microbial contamination.
- 3 The DEQ currently monitors 38 fixed stations along Saipan's most used west coast beaches on a
- 4 weekly basis for microbiological and chemical parameters. Four of these fixed stations occur
- 5 within the study area. During a more recent monitoring period (July 2010 to June 2011), water
- 6 quality standard exceedances were regularly observed for instantaneous and GM enterococci
- 7 measurements, DO, turbidity, and pH, although strong correlations were not noted.
- 8 As a comparison, average values of the 2010-2011 monitoring data for the wet season and dry
- 9 season were also calculated. No significant correlation between the season and the water quality
- parameters were observed for the 2010-2011 monitoring data, which is not entirely surprising
- given the short period of time analyzed. This may indicate that other factors play a role in the
- 12 transport of contaminants to the lagoon. There may be periodic releases of pollutants not
- associated with rainfall, a better system of contaminant uptake, a natural filtration or buffering of
- stormwater runoff prior to discharging into the lagoon, or a difference in upgradient land use.
- 15 The lagoon water sample results are included in Appendix C.8.

This page is intentionally left blank.

#### 5. RESTORATION ALTERNATIVE EVALUATION

- 2 In order to achieve the overall project goal of restoring the lagoon aquatic ecosystem structure,
- 3 function, and dynamic processes to a less degraded and more natural condition, restoration
- 4 alternatives were formulated with the goal of restoring the ecosystem to be self-sustaining in its
- 5 substantially modified environment. This section discusses ecosystem restoration policy, the
- 6 restoration alternative formulation process, the evaluation of restoration alternatives using cost
- 7 effectiveness (CE)/incremental cost analysis (ICA), as required by the Economic and
- 8 Environmental Principles and Guidelines for Water and Related Land Resources Implementation
- 9 Studies developed by the Water Resources Council (WRC) (WRC, 1983), and the selection of
- 10 the best restoration alternative. The CE/ICA was conducted using the USACE Institute of Water
- 11 Resources (IWR) Planning Suite Decision Support Software. A detailed description of the
- processes used as part of the CE/ICA for the evaluation of the restoration alternatives is included
- in Section 5.9.

1

#### 14 5.1 ECOSYSTEM RESTORATION POLICY OVERVIEW

- 15 Applicable policy governing USACE restoration projects include the Planning Guidance
- Notebook (ER 1105-2-100) and the Ecosystem Restoration Guidance (ER 1165-2-502 in support
- of ER 1165-2-501). Ecosystem restoration reestablishes a self-maintaining state that optimally
- should require very little human intervention.
- 19 Additionally, the entire ecosystem is the target of transformation by restoration, as opposed to a
- 20 specific species or a single component of habitat. Ecosystem restoration includes the entire
- 21 biotic community together with its physical environment, considered as an integrated unit (EP
- 22 1165-2-502). Often, only partial ecosystem restoration is practical, but the parts restored are
- done so holistically.
- 24 According to USACE policy requirements, restoration projects should conform to the following
- 25 constraints:
- the project should restore ecosystem structure, functions and values;
- the project should result in improved environmental quality;
- the sum of all monetary and non-monetary benefits should exceed the sum of all monetary and non-monetary costs;
- the measures taken to improve environmental quality should result in a more naturalistic and self-regulating system; and
- the measures should reestablish, to the extent possible, a close approximation of pre-existing conditions.
- Constraints specific to this study are included in Section 3.4.

#### 1 5.2 RESTORATION PLAN FORMULATION PROCESS

- 2 Restoration plan formulation strategies are based on guidelines set forth by the USACE
- 3 Ecosystem Restoration Planning and Evaluation Program. There are two primary principles
- 4 applied when determining plans:
- 5 1. Plans must meet each of the planning objectives without violating any constraints such as regulatory, economic, or social constraints.
  - 2. Plans must be based on institutional, technical, and public variables that are important to the entities involved (i.e., local cooperators, community, and USACE).
- 9 In order to fulfill the above principles, USACE guidelines offer the following criteria that a restoration plan must meet:
- must address the objectives of the project;
- must define the management measures that are required for the alternative;
- must be able to estimate the total cost of the alternative; and
- must be able to estimate a positive, quantifiable output.
- 15 In an effort to find the best possible solution for areas in need of restoration, alternative
- 16 restoration plans have been developed as part of the formulation process. Exploring and
- developing alternative plans is beneficial because it leads to the best possible solution by
- 18 encouraging creative thinking, allowing a broad view of the natural resources and planning
- 19 perspective, and promoting a greater understanding of natural processes, risks, and concerns
- associated with the project.

#### 21 5.3 FORMULATION OF ALTERNATIVE PLANS

- 22 The following management measures were considered during the initial alternative formulation
- 23 process:

7

- no action;
- capturing and pumping contaminants offshore;
- erosion control; and
- detention basins.
- 28 The no action alternative was considered to be unresponsive to the needs of the local sponsor and
- 29 was eliminated from further evaluation. The no action alternative was, however, included in the
- 30 alternatives analysis in the EA (Appendix A) as well as in the CE/ICA as required by the Council
- of Environmental Quality (CEQ) regulation 40 Code of Federal Regulations (CFR) Section
- 32 1502.14(d).
- Capturing and pumping contaminants offshore was eliminated from further evaluation because
- 34 CNMI stated that they cannot afford to maintain the mechanical pumps. In addition, this

- 1 management measure would not fulfill the objective of this study since it would not reduce the
- 2 amount of nutrients/sediment entering the lagoon but would rather relocate them offshore. This
- 3 would not result in an overall restoration of the lagoon ecosystem, which is the ultimate goal of
- 4 this study; therefore was not carried forward for further evaluation.
- 5 Erosion control within the upper portion of the watershed was not carried forward for further
- 6 consideration because it was not considered feasible to manage or control the widespread areas
- 7 within the watershed that contribute to the input of sediment/nutrients to the lagoon via
- 8 stormwater runoff. Many roads remain unpaved within the watershed, and clearing of natural
- 9 vegetation that makes the native soil susceptible to erosion is expected to increase with the
- 10 increased urbanization that is expected to occur within the study area. It was considered
- inefficient and impractical to consider implementing erosion control in all of these areas.
- 12 Although not carried forward for consideration as one of the management measures, erosion
- 13 control including paving or armoring unpaved roads, land use controls, public education,
- reforestation, and enforcing existing CNMI regulations for new construction projects to reduce
- or control the amount of sediment and runoff generated within the study area are recommended
- as one of the local BMPs to be implemented by the CNMI Government in conjunction with the
- management measure recommended in this study (see Section 5.11.5).
- 18 Construction of detention basins was considered the most cost effective and efficient
- 19 management measure in addressing the objectives of the study by efficiently collecting the
- 20 majority of sediment, nutrient, and contaminant laden runoff that would otherwise become
- 21 directly washed into the lagoon. The detention basins would capture and temporarily retain
- stormwater runoff from the upper watershed and allow suspended sediment and nutrients to
- settle out before stormwater is released to the lagoon, thereby reducing the amount of sediment
- 24 and nutrients that is transported to the lagoon. Sources of excess sediment, nutrient, and
- 25 contaminants that reach the lagoon are spread out throughout the study area, and construction of
- detention basins would be most efficient in collecting the runoff from the upper watershed prior
- 27 to it reaching the lagoon; therefore, was carried forward for further evaluation. As discussed
- 28 further in the following section, three detention basin sites within the study area were selected.
- 29 each with three storage capacities. A combination of two or more of these detention basins sites
- 30 were considered in formulating and evaluating a restoration alternative that would best achieve
- 31 the study objectives.

## 5.4 DESCRIPTION OF FORMULATION ALTERNATIVES

- 33 Three detention basin sites were considered to achieve the overall project goal of restoring the
- 34 Saipan Lagoon aquatic ecosystem structure, function, and dynamic processes to a less degraded
- and more natural condition. Dual-purpose type uses, such as soccer fields or parks, for the
- detention basins were originally considered but the project sponsor evaluated the level of effort
- that would be required for maintenance and upkeep and determined that it was impractical and
- 38 could not be supported. Three sizes of dry detention basins were designed for each of the three
- 39 sites, corresponding to the expected influx of water during a two-year rainfall event, a five-year
- 40 rainfall event, and a 10-year rainfall event. There are thus a total of nine possible detention
- 41 basins over three different sites. A detailed description and design for each detention basin are
- 42 included in the Preliminary Drainage Design Report prepared for the project (Appendix F).

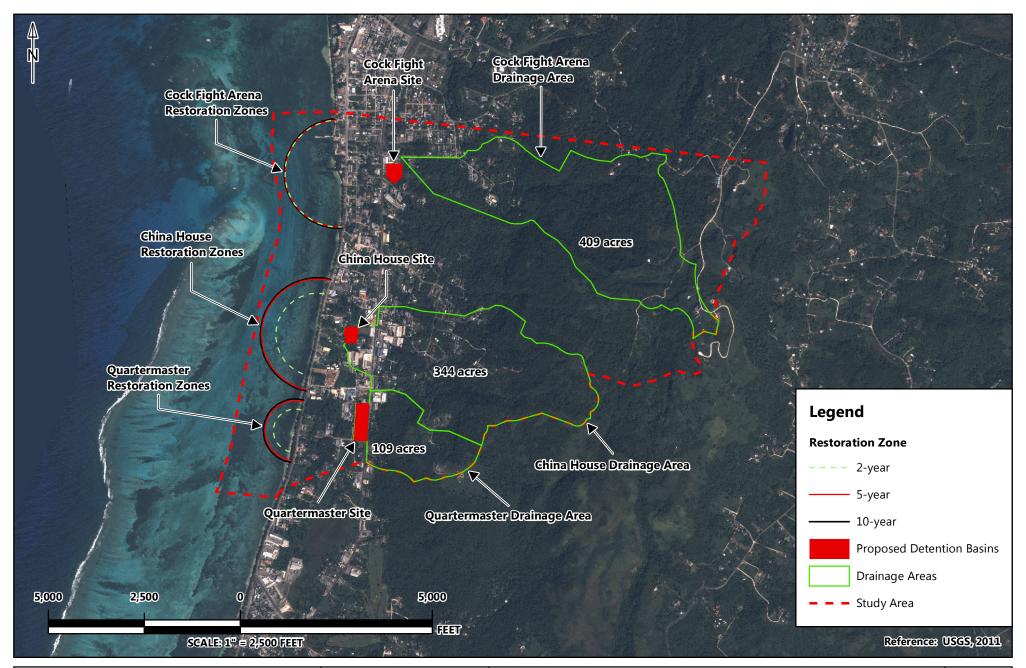

- 1 The three sites evaluated through the CE/ICA are located within the southern portion of the West
- 2 Takpochao watershed (Figure 7). The three sites were selected based on available vacant land
- 3 within the vicinity of Beach Road and Middle Road, and had to meet the requirement of being
- 4 low-lying areas that flood during heavy rains. Placement of a detention basin at a location where
- 5 stormwater runoff naturally accumulates was considered most appropriate in capturing runoff
- 6 that flows down the steep upper/inland part of the watershed. The three sites were evaluated in
- 7 terms of the amount of freshwater they could hold (capacity), the percent of the watershed that
- 8 would drain into the detention basin, and the relative amount of sediment, hazardous runoff, and
- 9 runoff loading they would receive compared to the amount generated within the entire study
- 10 area.

#### 11 **5.4.1** China House Site

- 12 The proposed China House site is approximately 2.8 acres in area and is located in the
- mid-southern portion of the study area, about halfway between Middle and Beach Roads. The
- 14 China House site occurs between Middle Road, across from the Pizza Hut building, and Beach
- Road near the China House restaurant. Topographically, the site is characterized by a natural
- drainage channel that flows to an outfall located along Beach Road in the center of the proposed
- site. The remaining site area is predominantly flat to slightly sloping (approximately 3.5%)
- 18 toward Beach Road and the lagoon.
- 19 The site currently serves as a natural drainage area for surface water from Middle Road and the
- 20 upper parts of the Gualo Rai area. Surface water reaches the lagoon through this area via surface
- 21 sheet flow and through the natural swale. There is currently a stormwater catch basin, located
- 22 along Middle Road adjacent to Pizza Hut, which collects surface water and diverts it beneath
- 23 Middle Road, and into the proposed detention basin site. During medium to large storm events,
- 24 the catch basin is insufficient to handle the volume of runoff and severe flooding occurs along
- 25 Middle Road at the Pizza Hut location. The topographic nature of this site is conducive to the
- 26 construction of a detention basin. The entire parcel of the site is currently publicly owned.

## 27 **5.4.2 Quartermaster Site**

- 28 The proposed Quartermaster site is approximately 6.6 acres and located at the southern-most end
- 29 of the study area. The site is located at the intersection of Quartermaster Road to the south and
- 30 Middle Road to the east. The site is currently vacant and overgrown, and generally slopes to the
- 31 southwest corner at approximately 4 to 5%. Several commercial and residential buildings lie
- 32 adjacent to the proposed site.
- Quartermaster Road, together with adjacent swales, serves as a major drainage route for surface
- 34 water during rain events. A drainage culvert is located beneath Middle Road at the intersection
- of Middle and Quartermaster Roads. The contributory area to surface runoff in this area includes
- 36 Middle Road and areas in the southern portion of the West Takpochao watershed. A detention
- 37 basin that would act as a settling pond for sediment and contaminants prior to discharging
- 38 surface water to the lagoon would be constructed at this site. The land required for the site is
- 39 currently privately owned.

## 5.4.3 Cock Fight Arena Site

1

2 The proposed Cock Fight Arena site is approximately 4.2 acres in area and is located on the east side of Middle Road at the northern end of the study area. 3 The closest cross street is 4 Commonwealth Road, located approximately 200 feet north of the Cock Fight Arena site. This 5 site is characterized by an abandoned quarry pit that occupies roughly one third of the site, in the 6 southeastern corner. The depression of the pit extends approximately ten feet in depth at its 7 deepest point. The remaining portion of the site is predominantly flat to slightly sloping (at 8 approximately 12%) in the direction of the quarry depression. The arena is currently located on 9 the western side of the site. Commonwealth Road acts as a major channel for surface runoff 10 water from a large contributory area during medium to large flood events. During rain events, 11 surface water streams down Commonwealth Road and into storm drains located at the 12 intersection of Commonwealth Road and Middle Road. The storm drain diverts the water north 13 toward Garapan and into a large surface water outfall that enters the lagoon near the Dai Ichi 14 Hotel. The area of restoration for this alternative thus may extend north of the study area 15 indicated on Figure 7. The contributory area for surface flow in this area includes many unpaved areas in the upper reaches of the watershed, leading to large amounts of sediment transport from 16 17 the upper reaches of the watershed to the lagoon. During medium to large rain events, the 18 current storm drain is insufficient to handle the amount of flow that occurs, resulting in severe flooding at the intersection of Commonwealth Road and Middle Road, and the surrounding 19 20 areas. The land required for the site is currently privately owned.

#### 21 5.5 REAL ESTATE REQUIREMENTS

- 22 USACE Civil Works policy requires the local sponsor provide all LERRD for the project
- 23 construction, operation, and maintenance of the proposed action.
- 24 The China House site would require acquisition of the entire lot (Parcel 1833) which is
- approximately 12,550 square meters (m<sup>2</sup>), and an estimated 1,823 m<sup>2</sup> of channel improvement 25
- 26 easement for the out-flow works. Additionally, permanent access encompassing approximately
- 27 972 m<sup>2</sup> from Middle Road to the site would be required since there is no direct public access to
- 28 the China House site.
- The Quartermaster site would require acquisition of the entire Parcel 1826-4 (approximately 29
- 30 1,507 m<sup>2</sup>), partial acquisition of Parcel 1826-R1 (approximately 2,000 m<sup>2</sup>, 3,780 m<sup>2</sup>, and 6,113
- 31 m<sup>2</sup> for the two-year, five-year, and 10-year design, respectively), and partial acquisition of Parcel
- 1822 (approximately 946 m<sup>2</sup>, 2,000 m<sup>2</sup>, and 2,500 m<sup>2</sup> for the two-year, five-year, and 10-year 32
- design, respectively). In addition, the Quartermaster site would require approximately 3,400 m<sup>2</sup> 33
- 34 for channel improvements to an existing swale.
- 35 The Cock Fight Arena site would require acquisition of the entire Parcel 078 D 01
- 36 (approximately 5,378 m<sup>2</sup>), partial acquisition of Parcel 25-4 (approximately 10,080 m<sup>2</sup>), and
- partial acquisition of Parcel EA 693-2 (approximately 1,140 m<sup>2</sup>). The cock fight arena, which is 37
- an approximately 12,500-m<sup>2</sup> structure located at the site would be acquired and demolished for 38
- 39 the project. In addition to the land required at the site, land area to accommodate approximately
- 40 2,200 linear feet of an 18-inch RCP for the diversion outlet flow is required for the Cock Fight
- 41 Arena site.

- 1 The Ouartermaster and Cock Fight Arena sites are both located on public roads and would have
- 2 readily available access for the implementation of the project. Additional information regarding
- 3 real estate requirements and associated costs for the project are included in the Real Estate
- 4 Planning Report (Appendix G).

13

14

#### 5.6 OPERATION AND MAINTENANCE

- 6 Implementation of detention basin systems would require ongoing maintenance in order to assure
- 7 their efficient and proper function. The local project sponsor will be responsible for the
- 8 operation and maintenance of the completed project. The following maintenance activities
- 9 should be conducted on an annual basis before the rainy season:
- 10 cutting of grass and weed removal in and around the basin and within the outlet swales;
- removal of accumulated sediment from the basin bottom to maintain designed capacity; 11 12 and
  - clearing of the basin inlet of debris, leafs, and any sediment.

#### 5.7 DESCRIPTION OF COSTS

- 15 Each detention basin was characterized in terms of its cost and expected benefits.
- preliminary CE/ICA was performed using cost estimates associated with each detention basin, 16
- 17 which was based on the sum of the real estate cost and construction cost. Real estate costs were
- 18 based on the Real Estate Planning Report prepared for the study (Appendix G). Construction
- 19 costs were developed for features identified in the Preliminary Drainage Design Report prepared
- 20 for the study (Appendix F). It is important to note that the estimated construction costs for the
- 21 detention basins do not include annual operation or maintenance costs. A recommended plan for
- 22 regular basin maintenance is included in Section 5.6.
- 23 Further refinement of the costs for a more realistic and accurate estimates were only completed
- 24 for the three alternatives which were retained following the preliminary CE/ICA. The three
- 25 alternatives retained for the final ICA were subjected to an Abbreviated Cost and Schedule Risk
- Analysis. From this risk analysis, the contingencies were calculated from a risk register with risk 26
- 27 elements collaborated on from the PDT. Once the contingencies were calculated, they were
- 28 placed in the Total Project Cost Summary (TPCS) along with the construction cost; real estate
- 29 cost; the planning, engineering, and design cost; and the construction management cost. All of
- 30 these costs were added together, along with the monies spent (i.e., the feasibility study cost) and
- 31 an escalation factor, to determine the total project cost of each alternative. TPCSs that include a
- 32 detailed breakdown of the total projects costs as well as the risk registers used to calculate the
- 33 contingencies for each alternative are included in Appendix H.
- 34 Table 5 shows the breakdown of the total project cost for each of the three alternatives retained
- 35 for the final ICA. Prefixes C, Q, or A refers to the China House, Quartermaster, or Cock Fight
- 36 Arena site, respectively. Numeral 0, 1, 2, or 3 refers to the no action, two-year, five-year, or
- 37 10-year design level, respectively. For example, A1 is the Cock Fight Arena 2-year design while
- 38 Q0 refers to the Quartermaster no action alternative.

7

26

27

Table 5: Cost Breakdown of Alternatives Retained for Final ICA

Combination	Construction Cost	Real Estate Cost	Planning, Engineering, and Design	Construction Management	Operation and Maintenance	Feasibility Study	Total Project Cost
C0 Q0 A1	\$2,986,000	\$1,062,000	\$2,345,000	\$576,000	\$5,600	\$1,483,000	\$8,451,000
C2 Q0 A1	\$7,769,000	\$1,680,000	\$2,561,000	\$785,000	\$9,800	\$1,483,000	\$14,277,000
C2 Q2 A1	\$10,723,000	\$2,288,000	\$2,674,000	\$912,000	\$12,300	\$1,483,000	\$18,079,000

#### Notes:

- 1. Construction and real estate costs include contingencies (see Appendix H).
- 2. Construction costs include post-construction monitoring costs.
- 3. Operation and maintenance costs shown are annual costs and are not included in the total project cost. The local project sponsor is responsible for providing operation and maintenance costs associated with the proposed detention basins.

#### 5.8 DESCRIPTION OF BENEFITS

- 8 Identification of a quantifiable environmental output serves to establish a measure of success for
- 9 the implemented restoration plan. Ideally, an environmental output should be quantifiable and
- 10 able to be documented. Commonly used environmental outputs are acres of habitat restored and
- habitat units restored (e.g., number of fish, plants, or acres of restored habitat).
- 12 The total lagoon acreage assumed to fall within the potential restoration zone includes the area of
- the lagoon from Quartermaster Road at the southern end to just beyond the Garapan Fishing
- 14 Dock at the northern end, the shoreline, and the extent of the seasonal macro-algal zone which
- occurs approximately 1,500 feet from the shoreline (Figure 7). This area totals approximately
- 16 371 acres. Implementation of restoration alternatives will most likely positively impact waters
- beyond this area, but for evaluation purposes these boundaries were chosen because they will see
- 18 the most dramatic changes.
- 19 For this study, the habitat restoration does not target a single fish or plant species. The premise
- 20 behind this restoration study is to restore the habitat of the entire nearshore lagoon aquatic
- 21 ecosystem. Therefore, the single habitat unit comparison developed for this study is based on the
- 22 number of acres of lagoon aquatic ecosystem (i.e., a nearshore, shallow, marine environment
- 23 with low abundances of seasonal macroalgae, and high abundances of sand and coral, with some
- 24 nearshore seagrass beds) that are restored. For the purpose of the CE/ICA, the following broad
- 25 habitat type category has been identified and quantified.
  - Nearshore lagoon habitat (1 lagoon habitat unit [LGHU] = 1 equivalent acre of restored nearshore lagoon water habitat).
- 28 Restored nearshore lagoon habitat refers to areas of the lagoon that would be positively impacted
- by the restoration alternative. One equivalent acre consists of the following quantifiable
- 30 components. It is assumed that improvement of the following components of the lagoon is
- 31 indicative of a restored and more natural condition of the lagoon state:
- 1. Decrease in percent cover of nearshore nuisance macroalgae.
- 2. Decrease in percent cover of nearshore and mid-lagoon seasonal macroalgae.
- 3. Lowered turbidity of nearshore water.

- 4. Decrease in incidents of microbial contamination of nearshore water.
  - 5. Decrease in nutrient concentration of nearshore lagoon water.
- While these components are quantifiable and will be used in conjunction with other components
- 4 to gauge the success of implemented restoration alternatives, it is not practical to assign
- 5 numerical values or projected goals to these components for purposes of the CE/ICA. It is also
- 6 important to note that success of the detention basins will be augmented by local implementation
- 7 of land use controls and other BMPs for contaminant reduction in the West Takpochao
- 8 watershed.

- 9 The number of LGHUs expected to be restored was calculated by first estimating the lagoon
- acreage that would be impacted by constructing each detention basin at the three sites. Each of
- 11 the three proposed detention basin designs has three different storage capacities of freshwater,
- and it is unlikely that the smallest basin would have a positive effect on all 371 acres of the
- 13 restoration zone. For each variable evaluated below, there is thus some application of the
- reduction factor "Y", calculated as:
- Y = (Average annual reduction in runoff for the detention basin design / average annual reduction in runoff for the 10-year detention basin design).
- 17 Appendix I includes the calculations used to estimate the average annual reduction in runoff for
- 18 each drainage basin.
- 19 The overall benefit was estimated by evaluating several factors such as hazardous waste runoff,
- sedimentation, storage capacity of the different basins and basin sizes, and runoff from PCAs.
- 21 Each of the following factors is expressed in terms of the LGHUs restored, in equivalent acres.
- 22 Individual tables showing how each of the factors was calculated are included in Appendix I.
- 23 FW: acres of lagoon restored by reducing freshwater runoff. FW was calculated by the
- 24 following four-step process:
- 1. divide the average annual runoff reduction of the basin by the average annual runoff reduction of that basin's 10-year estimate (Reduction factor "Y");
- 27 2. divide the drainage area for the basin by the total watershed area and convert to a percentage;
- 3. multiply the percentage calculated in step 2 by 371 (the total lagoon acres within the restoration zone); and
- 4. multiply the result of step 3 by the result of step 1. The result, FW, is an estimate of the acres of lagoon restored by reducing freshwater runoff for each of the nine potential designs.
- 34 As an illustrative example, the China House detention basin storage capacity of the two-year
- design was calculated at 4.765 acre-feet (ac-ft) (see Appendix F). FW for the two-year China
- House design was calculated as follows:

- 1 1. Y = 3.38315 / 6.35629 = 0.53225
- 2 2. 344 / 2000 \* 100 = 17.2%
- 3 344 is the drainage area for the China House detention basin, while 2000 is the drainage area of the entire watershed within the study area;
- 5 3. 371 acres \* 0.172 = 63.812 acres
- 371 is the total acreage of the "restoration zone" within the lagoon. It was multiplied by 0.1720, the percentage of the China House basin drainage area comprising the entire watershed area within the study area; and
- 9 4. 63.812 acres \* 0.53225 = 33.964 acres = FW
- 63.812 acres is the total acres of lagoon estimated to be restored by implementing the China House design. However, the two-year design does not have the same storage capacity as the 10-year design, and thus the factor calculated in step 1 is applied to account for the difference in storage capacity. FW for the China House two-year design is 33.964 acres.
- R: acres of lagoon restored by reducing runoff from runoff PCAs. This factor is based on the inventory of PCAs (Appendix C.5). To calculate R, the number of runoff PCAs within the drainage area for each drainage basin was divided by the total number of runoff PCAs identified
- in the study area. This factor was multiplied by the reduction factor Y, and by 371 (the total
- lagoon acres within the restoration zone). The result, R, is an estimate of the acres of lagoon
- 20 restored by reducing runoff PCAs for each of the nine potential detention basin designs.
- 21 H: acres of lagoon restored by reducing runoff from hazardous waste PCAs. This factor is
- 22 also based on the inventory of PCAs. To calculate H, the number of hazardous waste PCAs
- 23 within the drainage area for each detention basin was divided by the total number of hazardous
- waste PCAs identified in the study area. This factor was multiplied by the reduction factor Y,
- and by 371 (the total lagoon acres within the restoration zone). The result, H, is an estimate of
- the acres of lagoon restored by reducing hazardous waste PCAs for each of the nine potential
- designs.
- 28 S: acres of lagoon restored by reducing sedimentation. This factor is based on estimating
- 29 the number of acres of unvegetated and/or unpaved land within the drainage area for each
- detention basin, and within the entire study area, using Google Earth. To calculate S, the
- 31 estimated number of acres of unvegetated/unpaved land within the drainage area for each
- 32 detention basin was divided by the estimated number of acres of unvegetated/unpaved land
- 33 within the entire study area. This factor was multiplied by the reduction factor Y, and by 371
- 34 (the total lagoon acres within the restoration zone). The result, S, is an estimate of the acres of
- 35 lagoon restored by reducing sedimentation for each of the nine potential designs.

- 1 In addition to the runoff and hazardous waste PCAs, the PCA inventory identified several
- 2 sedimentation and nutrient PCAs within the study area (Appendix C.5). Because of the limited
- 3 number of nutrient PCAs that were identified within the study area, the calculation of nutrient
- 4 runoff was not considered in the LGHU calculation. The small number of nutrient PCAs was
- 5 considered to have a negligent impact on the outcome. The sedimentation factor calculation was
- 6 based on Google Earth and not on the number of sedimentation PCAs to include
- 7 unvegetated/bare land in the upper watershed within the study area that were not identified
- 8 during the PCA inventory. This method was considered to result in a more accurate estimate of
- 9 sedimentation that occurs within the study area.
- 10 An CE/ICA can only be conducted by comparing one cost parameter with one output parameter.
- 11 The four factors described above had to be combined into one output parameter. To accomplish
- this, a derived variable was calculated by weighting each of the four factors described above.
- 13 The derived variable LGHUs was calculated by the formula below.
- 14 LGHUs = 0.7FW + 0.1R + 0.1H + 0.1S
- 15 FW was assigned the heaviest weight because it is the primary vehicle for transportation of
- pollutants such as nutrients, hazardous materials, and sediment. The three other components
- were assigned equal weights because they all contribute to degradation of the lagoon habitat,
- albeit through different mechanisms.

- 19 Table 6 shows the calculated and derived variables used to conduct the preliminary CE/ICA.
- 20 The Cock Fight Arena site had identical storage capacities for the two-year and five-year
- designs, thus the values in the table are identical for the two-year and five-year design levels.

1

Table 6: Derived Variables Used to Conduct the CE/ICA

Management Measure	Site/ Design Level	Cost Estimate*	FW (acres)	R (acres)	H (acres)	S (acres)	LGHUs (equivalent acres)
C1	China House Two-Year	\$2,164,900	33.96	60.76	43.20	83.25	42.50
C2	China House Five-Year	\$3,376,000	61.27	109.61	77.93	150.19	76.66
C3	China House 10-Year	\$4,810,800	63.81	114.15	81.16	156.41	79.84
Q1	Quartermaster Two-Year	\$1,485,800	9.30	13.13	10.67	24.33	11.32
Q2	Quartermaster Five-Year	\$2,118,000	18.29	25.82	20.98	47.85	22.27
Q3	Quartermaster 10-Year	\$2,757,500	20.22	28.54	23.19	52.89	24.62
A1	Cock Fight Arena Two-Year	\$2,747,800	74.29	27.68	44.97	110.64	70.33
A2	Cock Fight Arena Five-Year	\$5,231,500	74.29	27.68	44.97	110.64	70.33
A3	Cock Fight Area 10-Year	\$5,686,300	76.61	28.54	46.38	114.10	72.53

- FW = Acres of lagoon habitat restored by reducing freshwater runoff.
- R = Acres of lagoon habitat restored by reducing runoff from runoff PCAs identified during the study.
- H = Acres of lagoon habitat restored by reducing runoff from hazardous waste PCAs identified during the study.
- S = Acres of lagoon habitat restored by reducing sedimentation.
- 2345678 LGHUs = lagoon habitat units, or equivalent acres of lagoon restored by implementing the chosen drainage basin design. This is a derived variable based on FW, R, H, and S.
- \*Cost estimate is based on the sum of the construction cost and real estate cost prior to adding contingencies.

#### 9 COST EFFECTIVENESS/INCREMENTAL COST ANALYSIS

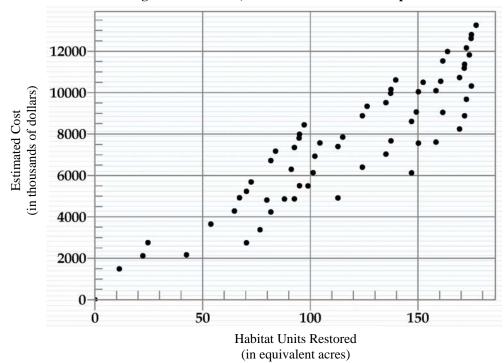

- 10 Economic analysis for environmental planning consists of two analytical processes that together
- 11 form the CE/ICA. CE analysis identifies the least cost alternative for each level of
- environmental output. Following the CE analysis, an ICA is performed to show the incremental 12
- 13 change in project cost with increasing levels of environmental output. The program relies upon
- 14 IWR Planning Suite Decision Support Software to complete the analyses as part of the following
- 15 four step process:
- 1. identify least-cost combinations; 16
- 17 2. identify the cost-effective combinations;
- 18 3. apply the ICA to the combinations identified in step 2 above; and
- 4. evaluate the combinations retained during step 3 above. 19

#### 20 5.9.1 Least-Cost Combinations

- 21 The cost estimates and LGHU variables from Table 6 were used to conduct the preliminary
- 22 CE/ICA. IWR-Planning Suite first builds all possible alternative plan combinations based on the
- 23 number of individual restoration sites, whether the sites can be combined with each other (i.e.,
- 24 implemented in tandem), or whether any of the sites are dependent on each other. Based on the
- assumptions that any or all of the three sites can be developed concurrently, at the no-build, 25
- two-year, five-year, or 10-year design level, there are 64 different plan combinations. All 64 26
- 27 combinations are shown on Figure 8 and listed in Appendix J.

Figure 8: All Plans, Estimated Cost versus Output

4 After building all possible plan combinations, inefficient combinations were eliminated by identifying combinations with identical levels of output and eliminating the higher cost 5

alternative. This process results in the identification of a least-cost combination for each level of 6

7 output produced by the initial list of combinable measures. Forty-eight (48) least-cost

8 combinations were identified in this step.

# **5.9.2** Cost-Effective Combinations

10 The 48 least-cost combinations identified in step 1 were analyzed for CE by identifying and 11

eliminating those combinations which produce a lower level of output for the same or greater

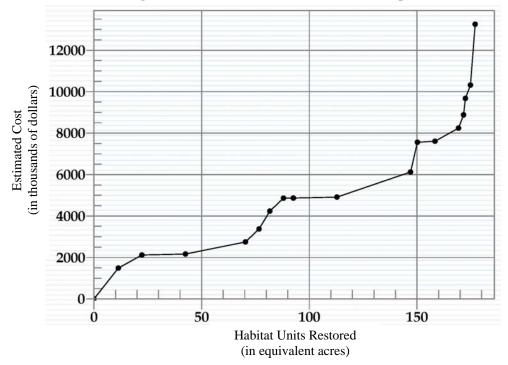

12 cost than another combination. The CE analysis indicates that there are 18 cost-effective plans.

The 18 cost-effective plans are shown in Figure 9 and listed in Appendix J.

14

13

Figure 9: Cost Effective Plans, Cost versus Output

23

10

11

# **5.9.3** Preliminary Incremental Cost Analysis

The 18 remaining cost-effective combinations were subjected to a preliminary ICA in which the incremental cost per output between successively larger (i.e., more output) combinations are determined, and the best buy plans as those combinations for which the incremental cost per output is lowest for a particular output level is identified. Seven best buy plans (i.e., the plan combinations with the lowest incremental cost per output level) were retained as a result of this analysis. These seven best buy plans are listed in Table 7 and shown in Figure 10. The tables and graphs generated with the IWR Planning Suite are included in Appendix J.

12

13

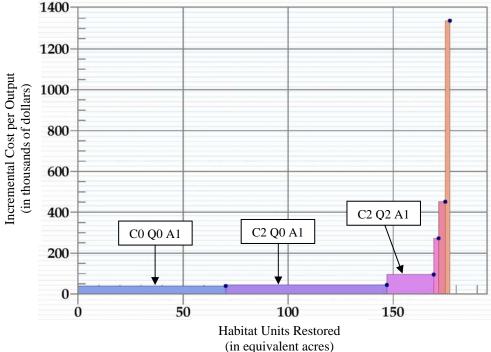

Table 7: Best Buy Plans, Preliminary Incremental Cost Analysis

Combination	Cost Estimate*	LGHUs (equivalent acres)	Average Cost per LGHU	Incremental Cost	Incremental Output (equivalent acres)	Incremental Cost per Output
C0 Q0 A0	\$0.00	0	\$0	\$0	0	\$0
C0 Q0 A1	\$2,747,800	70.33	\$39,069.0	\$2,747,800	70.33	\$39,069.0
C2 Q0 A1	\$6,123,800	146.99	\$41,660.2	\$3,376,000	76.66	\$44,037.5
C2 Q2 A1	\$8,241,800	169.26	\$48,692.6	\$2,118,000	22.27	\$95,114.1
C2 Q3 A1	\$8,881,300	171.61	\$51,752.8	\$639,500	2.35	\$272,359.5
C3 Q3 A1	\$10,316,100	174.79	\$59,021.0	\$1,434,800	3.18	\$451,621.0
C3 Q3 A3	\$13,254,600	176.98	\$74,8915	\$2,938,500	2.19	\$1,337,505.7

\*Cost estimate is based on the sum of the construction cost and real estate cost prior to adding contingencies.

Figure 10: Best Buy Plans, Preliminary Incremental Cost Analysis

#### 5.9.4 Evaluation of Alternative Plans

In accordance with ER 1105-2-100, the seven best buy plans were evaluated against the four criteria outlined in the Principles and Guidelines adopted by the Water Resources Council: completeness, efficiency, effectiveness, and acceptability. According to ER 1105-2-100, "completeness is the extent to which the alternative plans provide and account for all necessary investments or other actions to ensure the realization of the planning objectives, including actions by other Federal and non-Federal entities. Effectiveness is the extent to which the alternative plans contribute to achieve the planning objectives. Efficiency is the extent to which an alternative plan is the most cost effective means of achieving the objectives. Acceptability is the extent to which the alternative plans are acceptable in terms of applicable laws, regulations and public policies." Each combination was given a rating (i.e., poor, fair, good, very good, and excellent) for each criterion according to the ability of the alternative to achieve the objectives of the criterion. Table 8 presents the comparative analysis and ratings of the seven best buy plans.

The no action combination (C0 Q0 A0) was given the lowest ranking for all four criteria because it does not meet the study objectives and would not result in any benefits to the environment or the local economy. For the "Completeness" criteria, all combinations (besides the no action combination) was given a "Good" ranking considering that all plans will be implemented in consultation with and with the corporation of the local sponsor, and will also take into account any existing or future plans that would have any impacts on the objectives of this study.

For the "Efficiency" criteria, each combination was given a ranking based on its incremental cost per output (see Table 7 and Figure 10). The last three combinations (C2 Q3 A1, C3 Q3 A1, and

- 1 C3 O3 A3) were given the lowest ranking since their incremental costs are significantly higher
- 2 than the remaining combinations, adding merely two or three equivalent acres of restoration area
- 3 for a cost of over \$600,000 to almost three million dollars.
- 4 For the "Effectiveness" criteria, each combination was given a ranking based on the expected
- 5 equivalent acres of restoration area under each alternative. The last four combinations (C2 Q2
- 6 A1, C2 Q3 A1, C3 Q3 A1, and C3 Q3 A3) are expected to restore 169.26 to 173.98 equivalent
- acres of the lagoon. In addition, these combinations include the construction of a detention basin 7
- 8 at all three proposed sites, which in turn will result in restoration of all three areas of the lagoon;
- 9 therefore, was given the highest rankings.
- 10 For the "Acceptability" criteria, the highest rankings were given to all combinations (except for
- the no action combination) since all plans are expected to be in compliance with existing laws, 11
- 12 regulations, and public policies.

**Table 8: Best Buy Plans, Comparative Analysis** 

Combination	Completeness	Efficiency	Effectiveness	Acceptability
C0 Q0 A0	Poor	Poor	Poor	Poor
C0 Q0 A1	Good	Excellent	Good	Excellent
C2 Q0 A1	Good	Very Good	Very Good	Excellent
C2 Q2 A1	Good	Good	Excellent	Excellent
C2 Q3 A1	Good	Poor	Excellent	Excellent
C3 Q3 A1	Good	Poor	Excellent	Excellent
C3 Q3 A3	Good	Poor	Excellent	Excellent

14 15 The 5-tiered scale is a subjective scale that includes the following categories in decreasing order used to indicate the degree to 16 which criteria are met: Excellent, Very Good, Good, Fair, and Poor.

- 17 The no action combination (C0 Q0 A0) does not meet the study objectives and is considered to
- 18 be unresponsive to the needs of the local sponsor; therefore, is eliminated from further
- 19 evaluation. The remaining six combinations, with cost estimates and LGHU output ranging from
- 20 \$2,747,800 to \$13,254,600 and 70.33 to 176.98 equivalent acres, respectively are evaluated
- 21 below.
- 22 The first combination (C0 Q0 A1) results in 70.33 equivalent acres of restored area and would
- 23 most likely impact the northern part of the lagoon (Figure 7) where water quality violation
- 24 frequencies and metals contamination are observed to be highest based on currently available
- 25 baseline data of the lagoon. Since this combination does not involve the construction of
- 26 detention basins at the China House site or the Quartermaster site, areas to be restored with this
- 27 alternative is likely to be more pronounced within the northern section of the study area
- 28 compared to the southern portion of the study area. Compared to the without-project conditions,
- 29 the northern part of the study area would receive less input of nutrient and sediment load as well
- 30 as experience less frequencies of microbial contamination within the nearshore zone. Less input
- 31 of nutrient and sediment load would allow slower-growing coral and seagrass to develop within

the restoration zone and would prevent the area to become completely replaced by a macroalgae dominant community. This would result in more habitats available for fish and invertebrate species to thrive within the restoration zone. Reduction in the amount of nutrient and sediment input to the lagoon as well as the frequency of microbial contamination is expected to occur as soon as the alternative measure is implemented. Changes in the ecosystem structure of the study area may take up to several years until it is observed. This alternative would contribute to achieve the study objectives and is cost efficient, therefore is retained for further consideration.

The second combination (C2 Q0 A1) results in a total of 146.99 equivalent acres of restored area within the northern part of the lagoon (Figure 7) where water quality violation frequencies and metals contamination are observed to be highest as well as within the mid-portion of the lagoon (Figure 7). Since this combination does not involve the construction of a detention basin at the Quartermaster site, the very southern part of the study area is less likely to be impacted by this alternative. Compared to the without-project conditions, the northern part and the mid-section of the study area would receive less input of nutrient and sediment load as well as experience less frequencies of microbial contamination within the nearshore zone. As with the first combination, less input of nutrient and sediment load would allow slower-growing coral and seagrass to develop within these restoration zones and would prevent the area to become completely replaced by a macroalgae dominant community in the future, resulting in increased habitats that are available for fish and invertebrate species to thrive in. Reduction in the amount of nutrient and sediment input to the lagoon as well as the frequency of microbial contamination is expected to occur as soon as the alternative measure is implemented, and changes in the ecosystem structure of the study area is expected to take up to several years until it is observed. This alternative would contribute to achieve the study objectives and is cost efficient, therefore is retained for further consideration.

The third combination (C2 Q2 A1) results in a total of 169.26 equivalent acres of restored area within portions of the lagoon throughout the study area (Figure 7) since it involves the construction of a detention basin at all three proposed sites. Compared to the without-project conditions, all three restoration zones within the lagoon would receive less input of nutrient and sediment load as well as experience less frequencies of microbial contamination within the nearshore zone. The significant reduction in input of nutrient and sediment load to the lagoon by implementing this alternative would allow slower-growing coral and seagrass to develop, providing increased habitats available for fish and invertebrate species to thrive in. As with the previous two alternatives, reduction in the amount of nutrient and sediment input to the lagoon as well as the frequency of microbial contamination is expected to occur as soon as the alternative measure is implemented, and changes in the ecosystem structure of the study area is expected to take up to several years until it is observed. The larger output expected under this alternative corresponds to an increase in cost; however, it is retained for further evaluation considering that a significant portion of the lagoon is expected to be restored.

The last three combinations; C2 Q3 A1, C3 Q3 A3, result in a total of 171.61, 174.79, and 176.98 equivalent acres of restored area, respectively. Restoration zones for these alternatives would include areas throughout the study area since they would entail construction of detention basins at all three proposed sites. Compared to the without-project conditions, these

alternatives would result in reduction of input of nutrient and sediment to the lagoon as well as reduction in frequencies of microbial contamination within the nearshore zone. These outputs are expected to be observed immediately following the construction of the detention basins and would prevent the shift to a macroalgae dominated community within the restoration zones, allowing for coral and seagrass communities to develop, which in turn, will provide increased habitats for fish and invertebrate species within the area. The outputs expected under these alternatives are large; however the corresponding incremental costs are significantly high. These alternatives do not provide a cost-efficient means of achieving the study objectives; therefore are eliminated from further consideration.

# 5.9.5 Final Incremental Cost Analysis

The three alternatives retained for further consideration were subjected to an Abbreviated Cost and Schedule Risk analysis. Once the contingencies were calculated, they were placed in the TPCS to determine the total project cost for each alternative. The final ICA was performed using annualized total project costs instead of the cost estimates that were used for the preliminary ICA as well as using average annual outputs (Table 9 and Figure 11). The three alternatives are independent of each other, thus the output of each alternative is not dependent on any other alternative nor are the alternatives combinable. Annualization of total project costs and outputs were conducted using the IWR Planning Suite annualization tool. The tables and graphs generated with the IWR Planning Suite are included in Appendix J.

**Table 9: Final Incremental Cost Analysis** 

Combination	Average Annual Cost	Average Annual LGHUs (equivalent acres)	Average Annual Cost per LGHU	Incremental Annual Cost	Incremental Annual Output (equivalent acres)	Annual Incremental Cost per Output
C0 Q0 A1	\$300,375	4.22	\$71,182	\$300,375	4.22	\$71.18
C2 Q0 A1	\$458,532	8.82	\$51,991	\$158,157	4.60	\$34.38
C2 Q2 A1	\$723,889	10.16	\$71,280	\$265,356	1.34	\$198.59

Figure 11: Final Incremental Cost Analysis, Incremental Cost versus Output C2 Q2 A1 Annual Incremental Cost (in thousands of dollars) per Output C0 Q0 A1 C2 Q0 A1 Average Annual Habitat Units Restored

# 5.9.6 Plan Comparison

The first combination (C0 Q0 A1) has the lowest annual cost of all three final alternatives, which also corresponds to the lowest annual number of equivalent acres restored. The restoration area would be mostly observed within the northern section of the study area. The second combination (C2 Q0 A1) adds 4.6 annual equivalent acres of restored area in two distinct areas of the lagoon, which is a two-fold increase compared to the first combination. The jump in annual output is matched by an increase in annual cost from \$300,375 to \$458,532. Although the cost is much higher compared to the first combination, the average cost per LGHU and incremental cost per output is the lowest of all three final combinations.

(in equivalent acres)

The third combination (C2 Q2 A1) is the only combination that includes all three proposed detention basin sites. The incremental cost per output for this combination is much higher than the first two combinations. The increase in the annual output (from 8.82 to 10.16 equivalent acres) compared to the second combination corresponds to a double in annual incremental cost per output (from \$34.38 to \$198.59). This alternative is considered the most preferred considering that all three restoration zones corresponding to the three detention basin sites will be restored. However, the increase in annual incremental cost per output is not matched by its level of incremental output; therefore, this combination is considered the least preferred from a cost perspective.

#### 5.10 SELECTION OF PREFERRED ALTERNATIVE

Comparison of the three alternatives that were retained for the final ICA was carefully reviewed to select the preferred alternative. The comparison discussed in the previous section indicates that the third alternative (C2 Q2 A1) would result in the greatest amount of output but with a high cost. The first alternative (C0 Q0 A1) would be the most cost efficient; however, would have the least amount of output. The second combination (C2 Q0 A1) was considered to be

- 1 inbetween the first and third alternatives, with a cost and output inbetween the two. The average
- 2 cost per LGHU and incremental cost per output was the lowest; therefore, the second
- 3 combination was considered the most cost efficient when considering the unit cost per restored
- 4 acre of the lagoon.
- 5 As discussed earlier in Section 5.9.4, the completeness and acceptability of all three final
- 6 alternatives are considered to be equal. Efficiency of the three alternatives was ranked based on
- 7 their incremental cost per output, with the first alternative (C0 Q0 A1) having the highest ranking
- 8 based on its low cost and the third alternative (C2 Q2 A1) having the lowest ranking based on its
- 9 high cost. Effectiveness of the three alternatives was ranked based on the expected equivalent
- acres of restoration area under each alternative, with the third alternative (C2 Q2 A1) given the
- highest ranking based on its highest amount of output and the first alternative (C0 Q0 A1) having
- the lowest based on the least amount of output expected.
- 13 Based solely on cost, the first alternative (C0 Q0 A1) was considered the most preferred. The
- second and third alternatives (C2 Q0 A1 and C2 Q2 A1) were preferred over the first
- 15 combination because they involved construction of a detention basin at more than just one site,
- which would allow restoration in more than one area of the lagoon. The first alternative involves
- 17 construction of one detention basin at the Cock Fight Arena site, which corresponds to
- restoration within the northern section of the study area.
- 19 Because of funding constraints, the CNMI preferred alternative was the first alternative. The
- 20 PDT went back to review the existing data to determine whether it would be worth investing in a
- 21 project that involves construction of a single detention basin at the Cock Fight Arena site rather
- 22 than selecting an alternative that would involve construction of multiple detention basins that
- would result in restoration of more than one section of the study area.
- 24 Review of currently available baseline data indicates that water quality violation frequencies and
- 25 metals contamination are observed to be the highest within the northern section of the lagoon.
- The drainage area for the Cock Fight Arena site is the largest of all three sites (Figure 7), and it is
- 27 expected to result in a measurable improvement of the lagoon state by capturing a majority of
- 28 runoff that reaches Saipan Lagoon. Although the first alternative has the least amount of
- 29 expected equivalent acres of restoration area, the degree to which the lagoon will be restored is
- 30 considered to be significant considering that degradation is most advanced within the northern
- 31 section of the study area where restoration is expected to take place under this alternative. The
- 32 selected plan will restore 70.33 equivalent acres of lagoon habitat at an estimated total project
- selected plan win restore 70.33 equivalent acres of lagoon habitat at an estimated total pro-
- cost of \$8,451,000. Table 10 shows the cost breakdown of the preferred alternative.

Table 10: Cost Breakdown of Preferred Alternative

Preferred Alternative	Construction Cost*	Real Estate Cost*	Planning, Engineering, and Design*	Construction Management*	Feasibility Study	Total Project Cost
C0 Q0 A1	\$2,986,000	\$1,062,000	\$2,345,000	\$576,000	\$1,483,000	\$8,451,000

\*Costs include contingencies (see Appendix H).

34

### 1 5.11 IMPACTS OF SELECTED PLAN

- 2 The selected plan will restore the lagoon aquatic ecosystem to a less degraded and more natural
- 3 condition. Specific impacts of the selected alternative on various components of the lagoon
- 4 ecosystem, as well as additional benefits are discussed below.

# 5 5.11.1 Ecosystem Enhancement

- 6 The predominant focus of the preferred alternative is to restore the degraded Saipan Lagoon
- 7 aquatic ecosystem. The single most detrimental influence on the lagoon is the influx of
- 8 sediment, nutrient, and contaminant-laden runoff. The implementation of a detention basin
- 9 would serve to improve the overall function and health of the lagoon aquatic ecosystem by
- 10 capturing stormwater prior to it entering the lagoon, and allowing sediment and contaminants to
- settle out before the water is discharged into the lagoon.

# 12 5.11.1.1 Aquatic Ecosystem

- With a reduction of sediment, nutrients, and contaminants entering the lagoon, the aquatic
- ecosystem, including corals, fish, and seagrasses, will function more naturally (see Section 3.1).
- 15 Implementation of controls for runoff will also aid in limiting the otherwise unavoidable further
- degradation of the lagoon with future development within the West Takpochao watershed.
- 17 Ultimately, the intention of the preferred alternative is to reduce nonpoint source pollution, and
- thereby allow the return of seagrass and corals to dominance in currently degraded habitats.

# 19 **5.11.1.2 Endangered Species**

- 20 The Green Sea Turtle and the Hawksbill Sea Turtle, both endangered species, would benefit
- 21 from an increase in quality of the Saipan Lagoon habitats. Green Sea Turtles, in particular, feed
- 22 on seagrass; therefore an increase in healthy seagrass would result in an expansion of potential
- 23 foraging areas.

# **24 5.11.2 Water Quality**

- 25 Restoration of water quality is a key component of the preferred restoration alternative.
- 26 Detention basins serve to improve runoff water quality by allowing sediments and nutrients to
- settle out prior to its transport to the lagoon, leading to an improvement of lagoon water quality.
- 28 In addition to improving aquatic ecosystem function, improved lagoon water quality would be
- 29 conducive to the tourism industry of Saipan. Controlling and treating surface water flow
- 30 entering the lagoon, together with local policy changes that are part of the preferred alternative
- 31 (see Section 5.11.5), would most likely lead to a decrease in microbial contamination that has
- 32 recently become a significant concern for beach front hotels and tourism-related businesses.

# **5.11.3 Flood Control**

- 34 The preferred alternative would offer limited mitigation of localized flooding within the study
- 35 area. Currently, the drainage system within the study area is insufficient to handle even medium
- 36 sized rain events. Collection and conveyance systems that would be implemented for the
- 37 restoration alternative would aid in controlling the localized flooding that occurs frequently in
- 38 the area. These conveyance systems would be a significant improvement over the current
- 39 minimal stormwater drainage system.

# **5.11.4** Recreational/Aesthetic Improvements

38

39

40

- 2 The cumulative impact of implementing the preferred alternative could include not only
- 3 preserving the natural environment, but also improving the quality of living for residents, the
- 4 atmosphere for local businesses, and tourist attractions. In particular, reducing the presence of
- 5 nuisance macroalgae is an active issue of concern for the tourism/hotel industry that would be
- 6 improved or resolved in the study area. Reduction of nutrient levels that promote microalgal
- 7 growth, along with reduced input of silt and sediment, would improve water clarity, which is
- 8 another benefit from a recreational perspective.

# 9 5.11.5 Recommended Local Best Management Practice

- 10 It is strongly recommended that the CNMI Government implement the following local BMPs to
- 11 further reduce contamination and degradation of Saipan Lagoon. These BMPs were identified
- based on land-use practices or activities on land that generate a majority of nutrients, sediment,
- or contaminants that reach the lagoon via stormwater runoff (DEQ, 2010). Each of the BMPs
- will result in reduction of at least one or more of these contaminant sources, and will contribute
- towards a less degraded and more natural condition of the lagoon.
  - 1. Pave or armor unpaved roads that contribute a majority of sediment to the lagoon, which would significantly reduce the amount of sediment that is washed into the lagoon via stormwater runoff.
  - 2. Conduct sanitary sewer surveys and repair damaged portions of the sewer system, which would reduce the amount of nutrients and contaminants that reach the lagoon via stormwater runoff or infiltration through the ground.
  - 3. Extend sewer lines to replace septic and cesspool systems within the study area, which would reduce the amount of nutrients and contaminants that reach the lagoon during accidental spills or flooding during large storm events.
  - 4. Implement watershed management measures such as land use control measures, public education, reforestation, etc. in order to control activities that involve clearing of natural vegetation. Clearing of natural vegetation not only disturbs the natural soil, but also renders the land more susceptible to runoff and erosion. Raising public awareness and restoring the natural vegetation will contribute to a watershed that is less susceptible to runoff and erosion, thereby reducing the amount of sediment, nutrients, and contaminants that are directly transported to the lagoon via runoff.
  - 5. Establish BMPs for the island with respect to trash and waste disposal in order to reduce the amount of nutrients or hazardous waste that may leach through the ground or become transported to the lagoon via stormwater runoff.
  - 6. Enforce existing CNMI regulations for sediment and runoff capture for new construction projects in order to control the amount of sediment and runoff generated during ground disturbing activities.
  - 7. Enact land use restrictions on placement of livestock farms and other sources of nutrients, which would contribute to controlling and reducing the amount of nutrients that are washed into the lagoon during rain events.

- 1 Implementation of some or all of these BMPs will enhance the environmental quality of Saipan
- 2 Lagoon; however, the success of this project is not dependent upon implementation of these
- 3 BMPs.

14

21 22

23

24 25

26

27

28

- 4 This DPR includes a post-construction monitoring plan that will measure the success of the
- 5 detention basins for the five years immediately following construction (Appendix K). BMPs
- 6 were not considered in the plan development.
- 7 It may be difficult to distinguish the degree of lagoon restoration attributable to the detention
- 8 basins from the degree of lagoon restoration attributable to the implementation of BMPs. The
- 9 most effective way to individually quantify the benefits is to establish or re-establish the baseline
- 10 conditions of the lagoon immediately following implementation of BMPs. The following
- options provide a suggested framework for considering baseline conditions and evaluating
- 12 project success and BMP success:
  - 1. The data included in this DPR establishes the baseline condition of the Saipan Lagoon aquatic ecosystem prior to implementation of detention basins or BMPs. It will be used as the baseline for measuring success of detention basin installation.
    - 2. If BMPs are implemented prior to the construction of the detention basins, the baseline conditions of the Saipan Lagoon aquatic ecosystem should be reestablished via a new round of sampling (aquatic habitat assessment, water quality parameters, stormwater quality, and sediment delta surveys).
    - 3. If BMPs are implemented concurrently with construction of the detention basins, the first sampling event conducted 'post construction' will be used as the new baseline for evaluating the effectiveness of constructing the detention basins
    - 4. If BMPs are implemented at some point during the five years following construction of the detention basins, the sample data will be evaluated to look for a significant change in the aquatic ecosystem that can be specifically attributed to the BMPs; otherwise the continued improvement of the aquatic ecosystem will be attributed to the construction of the detention basins.

# 5.12 POST CONSTRUCTION MONITORING PLAN

- 29 The data collected during the course of this study will serve as a baseline measurement of
- 30 "before project" conditions. In order to properly and accurately assess the progress of ecosystem
- 31 restoration, it would be best to couple both marine habitat health data with water quality
- 32 measurements. An increase in water quality should be accompanied by a restoration of critical
- ecosystem components. A five-year post-construction monitoring plan (Appendix K) should be
- implemented to compare the aquatic ecosystem before project conditions to the post-construction
- 35 state. Specific components of the plan include:
- weekly assessment of the presence and abundance of nearshore nuisance macroalgae;
- re-assessment of the inshore lagoon area;
- continued weekly nearshore lagoon water sampling, compared to rainfall data;

9

10

11

12

17

18 19

20

- stormwater sample collection and analysis at influent and effluent points of the drainage basin(s); and
- resurvey of sediment deltas at Drains 4, 6, and 11.
- The project could be deemed a success if at least five of the following benchmarks were achieved:
- 1. Reduction in the frequency and abundance of nearshore, fast growth nuisance macroalgae (at least a 20% reduction in percent cover or 25% reduction in days of occurrence).
  - 2. Decrease in the abundance of seasonal macroalgae in the nearshore and mid-lagoon regions (at least a 20% reduction in percent cover).
    - 3. Decrease in turbidity of nearshore waters, particularly following storm events (at least a 25% reduction in number of violations of DEQ water quality standards for turbidity).
    - 4. Decrease in microbial contamination in nearshore waters (at least a 25% reduction in number of violations of DEQ water quality standards for microbial contamination).
      - 5. Decrease in nutrient levels in nearshore waters (at least a 25% reduction in number of violations of DEQ water quality standards for nutrients).
      - 6. Decrease in contaminant (i.e., turbidity, microbial, and nutrient) concentrations in stormwater exiting the detention basins (at least a 25% reduction in number of violations of DEQ water quality standards for turbidity, microbial contamination, and nutrients).
      - 7. Decrease in sediment load entering Saipan Lagoon at mitigated drainages (at least a 10% reduction in sediment delta area).
- Table 11 summarizes the benchmarks and their corresponding reduction goals.

**Table 11: Post-Construction Monitoring Benchmarks and Reduction Goals** 

	Monitoring Parameter	Reduction Goal
1	Nearshore, fast growth nuisance	20% reduction in percent cover or
1	macroalgae	25% reduction in days of occurrence
2	Nearshore/mid-lagoon, seasonal macroalgae	20% reduction in percent cover
		25% reduction in number of
3	Turbidity in nearshore waters	violations of CNMI DEQ water
		quality standard
4	Microbial contamination in nearshore	25% reduction in number of
	waters	violations of CNMI DEQ water
	waters	quality standard
		25% reduction in number of
5	Nutrient levels in nearshore waters	violations of CNMI DEQ water
		quality standard
	Contaminant (turbidity, microbial, and	25% reduction in number of
6	nutrient) concentrations in stormwater	violations of CNMI DEQ water
	existing detention basin	quality standards
7	Sediment load entering the lagoon	10% reduction in sediment delta
/	Scannent toda entering the tagoon	area at mitigated drainage

- 1 Achievement of the first two benchmarks is less certain than the remaining five benchmarks
- 2 because factors that are not directly linked to the proposed detention basins such as groundwater
- 3 or other drainages may also affect the outcomes. The last five benchmarks are directly linked to
- 4 the proposed detention basins and should be achieved by the project.
- 5 The following table summarizes the risk register to capture the risk of not reaching these goals
- 6 and risks associated with factors that may have impacts on accomplishing the reduction goals.

**Table 12: Post-Construction Monitoring Risk Register** 

Risk Name	Probability (low, medium, high)	Mitigation	Contingency
Less than five of the benchmark reduction goals met	Medium	<ul> <li>Ensure operation and maintenance of the detention basin (see Section 5.6) is conducted regularly to maintain the designed filtration capacity</li> <li>Ensure local BMPs identified in Section 5.11.5 are implemented</li> </ul>	<ul> <li>Review factors within the study area that may be influencing monitoring parameter</li> <li>Adjust reduction goals or extend monitoring period if necessary</li> </ul>
Large storm event during post- construction monitoring period	High	Ensure operation and maintenance of the detention basin is conducted at all times to ensure maximum capacity	Reevaluate baseline conditions and adjust benchmark goals if necessary.
Large sewage spill during post- construction monitoring period	Low	Ensure sewage system is maintained properly	Reevaluate baseline conditions and adjust benchmark goals if necessary.

- 8 Since unpredicted events or unknown/unpredicted factors may influence the outcome of the project, it is important to allow for adaptive management if it becomes necessary. As stated
- earlier in this section, success of the project is dependent upon proper operation and maintenance
- of the detention basin as well as implementation of local BMPs. In the event that less than five
- of the benchmark reduction goals are met, factors within the study area that may be contributing
- to the increased input of contaminants (nutrients, sediments, or contaminants) will be reviewed,
- and if necessary, the monitoring period may be extended or the reduction goals may be adjusted.
- 15 In case of a large storm event or sewage spill, it may become necessary to reevaluate the baseline
- 16 conditions since these events are expected to impact the monitoring parameters.

# 6. PROJECT IMPLEMENTATION

- 2 The success of the project is highly dependent upon local cooperation and understanding of what
- 3 their roles and responsibilities are during the implementation of the project. The following
- 4 sections identify the project local cooperators and sponsors, as well as their roles and financial
- 5 obligation that will need to be fulfilled.

# 6 6.1 LOCAL COOPERATION

- 7 Local cooperators involved with this project include the following:
- 8 CRMO;
- 9 DEQ;

- 10 DFW;
- CNMI Department of Public Works (DPW); and
- 12 MMT.
- 13 CRMO is the local sponsor for this project. It is the role of the CNMI Government, to fulfill the
- 14 following for the project:
- Provide all LERRD required for the project.
- Provide all access routes and relocations of utilities necessary for project construction, and for operation and maintenance.
- Contribute in cash, the local share of project cost (the Federal contribution limit is five million dollars).
- The local sponsor will be responsible for all operations and maintenance.

# **EXECUTIVE SUMMARY**

2 The United States (U.S.) Army Corps of Engineers (USACE) and local sponsor Commonwealth of the Northern Mariana Islands (CNMI) Coastal Resources 3 4 Management Office (CRMO) are proposing to restore the aquatic ecosystem of Saipan Lagoon. Urban runoff from upland areas over the years has led to degradation of the 5 lagoon's marine ecosystems. The Proposed Action is to construct a detention basin to 6 7 capture sediment, nutrients, and contaminants in runoff waters on Saipan for purposes of 8 restoring the lagoon's aquatic ecosystem. Improvement in the lagoon water quality is 9 needed in order to maintain the ecological health and function of the lagoon which is a vital cultural, recreational and economic resource for Saipan. Stormwater capture and 10 11 filtration through environmentally sound engineering means is necessary to address the 12 need to improve the natural ecology of Saipan Lagoon. This project is authorized under

- of the Water Resources Development Act (WRDA).
- 15 This Environmental Assessment (EA) prepared in accordance with the National

the Continuing Authorities Program (CAP) section 206-Aquatic Ecosystem Restoration

- 16 Environmental Policy Act (NEPA) of 1969 as amended, examined the No Action and
- 17 Preferred ("Build") Alternative. Under NEPA the purpose of an EA is to evaluate
- whether an action may result in a significant environmental impact. Because an
- 19 engineering solution is needed to address the lagoon's water quality and ecosystem
- degradation, the No Action scenario is not acceptable as it does not meet the project's
- 21 purpose and need. An Ecosystem Restoration Report (ERR) (Environet, 2013) prepared
- 22 concurrently with this report focuses on field studies, alternatives analysis and an
- 23 incremental cost analysis of the numerous alternatives evaluated to recommend a
- 24 Preferred Alternative that would best restore the lagoon to a less degraded, more natural
- 25 condition.

1

- 26 The Draft EA examined the following environmental impact categories: Geology and
- 27 Soils; Solid and Hazardous Waste; Noise; Climate and Air Quality; Hydrology and Water
- 28 Quality; Traffic and Circulation; Biological (Fish, Wildlife and Plants) Resources;
- 29 Historical and Cultural Resources; Land Use; Visual Resources; Recreation/Resource
- 30 Use; Economic and Social Resources and Cumulative Impacts.
- 31 Project related construction activities may result in significant short-term environmental
- 32 impacts which could be mitigated to less than significant. Fugitive dust and noise
- 33 generated by construction equipment such as backhoes, jack hammers, and large trucks
- will be mitigated by best management practices (BMPs) such as use of dust screens, site
- 35 watering, and proper maintenance of contractor equipment. Beneficial long term
- 36 environmental impacts expected are improved water quality and resultant restoration of
- 37 Saipan Lagoon's health and ecosystem function.
- 38 As described in the Draft EA, the Preferred Alternative and No Action alternative were
- analyzed to determine the potential impacts and appropriate mitigation measures for
- 40 those impacts. Thus, based on the evaluation conducted, the USACE has determined that
- 41 a Finding of No Significant Impact (FONSI) is anticipated.

# 1. INTRODUCTION

# 2 1.1 SCOPE AND AUTHORITY

- 3 The United States (U.S.) Army Corps of Engineers (USACE) is conducting an
- 4 Environmental Assessment (EA) for the restoration of the Saipan Lagoon Aquatic
- 5 Ecosystem. The Commonwealth of the Northern Mariana Islands (CNMI) Coastal
- 6 Resources Management Office (CRMO) is the local sponsor of the Proposed Action
- 7 analyzed in this EA. This document is prepared in accordance with the National
- 8 Environmental Policy Act (NEPA) of 1969, as amended, Council on Environmental
- 9 Quality (CEQ) regulations (40 Code of Federal Regulations (CFR) 1500-1508), USACE
- Regulation 33 CFR Part 230; Procedures for Implementing NEPA, as well as the Water
- 11 Resources Development Act of 2007, to evaluate the economic and environmental
- 12 consequences of the Proposed Action.
- 13 Under NEPA the purpose of an EA is to evaluate whether or not an action may have a
- significant environmental impact. Based on the study contained in the EA, it will be
- determined whether the Proposed Action will significantly affect the environment. A
- 16 Finding of No Significant Impact (FONSI) will be issued if no adverse environmental
- impacts are anticipated. If it is determined that the Proposed Action will result in adverse
- environmental impacts, an environmental impact statement (EIS) will be prepared.
- 19 The USACE is authorized under the Continuing Authorities Program (CAP) section 206-
- 20 Aquatic Ecosystem Restoration of WRDA to provide design and construction assistance
- 21 to non-Federal interests for aquatic ecosystem restoration and protection projects that are
- 22 cost-effective and in the public interest. The USACE evaluates projects that benefit the
- environment by restoring, improving, or protecting aquatic habitat for plants, fish, and
- 24 wildlife. Projects typically involve restoration of aquatic ecosystems in rivers, lakes,
- wetlands, and lagoons.
- 26 Applicable policy governing USACE restoration projects include the Planning Guidance
- Notebook (ER 1105-2-100), Ecosystem Restoration Guidance (EP 1165-2-502 in support
- of ER 1165-2-501), Engineer Regulation 200-2-2: Procedures for Implementing NEPA,
- and the principles and guidance document approved by the Water Resources Council
- 30 (WRC) in 1983 (WRC, 1983). Ecosystem restoration purpose differs from the majority
- of USACE projects in that the goal is to reverse, at least in part, past influence of human
- 32 action. Instead of building an environment-altering structure such as a bridge or a dam,
- 33 restoration projects attempt to restore ecosystems to a close approximation of their
- 34 natural state. Ecosystem restoration reestablishes a self-maintaining state that optimally
- 35 should require little human intervention.
- 36 Additionally, the entire ecosystem is the target of transformation by restoration, as
- 37 opposed to a specific species or a single component of habitat. Ecosystem restoration
- 38 includes the entire biotic community together with its physical environment, considered
- as an integrated unit (EP 1165-2-502). Often only partial ecosystem restoration is
- 40 practical, but the parts restored are done so holistically.

- 1 According to USACE policy requirements, restoration projects should conform to the following constraints:
  - the project should restore ecosystem structure, functions and values;
  - the project should result in improved environmental quality;
    - the sum of all monetary and non-monetary benefits should exceed the sum of all monetary and non-monetary costs;
    - the measures taken to improve environmental quality should result in a more natural and self-regulating system; and
    - the measures should reestablish, to the extent possible, a close approximation of pre-existing conditions.

This EA incorporates guidance established under 40 CFR Part 230.10(a). Under these guidelines the USACE requires that the least environmentally damaging practicable alternative (LEDPA) is considered, so long as the alternative does not have other significant adverse environmental consequences. The guidance also includes the following environmental analysis:

# Alternative Analysis

- The No Action Alternative.
- The Preferred Alternative

# **Environmental Impact**

• Assess the impact of each alternative on the aquatic ecosystem and the surrounding environment overall. Compare the impact of the alternatives and identify which alternative is the LEDPA and why. Identify practicable alternatives that have no significant or easily identifiable difference in impact from the LEDPA.

# **Practicability**

- Address the practicability of the above alternatives. Practicability depends on cost, technical, and logistic factors. To be practicable, an alternative must be available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall purposes. If it is otherwise a practicable alternative, an area not presently owned by the applicant which could reasonably be obtained, utilized, expanded, or managed in order to fulfill the overall purpose of the proposed activity should be considered. Technical and logistical factors that should be considered include, but are not necessarily limited to: access, transportation needs, utilities, topography, and available construction techniques.
- Address the consequences on the applicant and the public of not implementing the project.

Mitigation

1

2

3

4

5

20

If the alternative identified as the LEDPA still has adverse impacts to the aquatic ecosystem, identify how it is proposed to further minimize those impacts and provide compensatory mitigation for any remaining unavoidable adverse impacts.

# 6 1.2 STUDY AREA LOCATION

- 7 The location of this restoration study is the Saipan Lagoon, located in Saipan, CNMI.
- 8 The study area encompasses the southern portion of the West Takpochao watershed. The
- 9 study area extends from Quartermaster Road to just past the Fishing Base in Garapan
- along the western shoreline of the island of Saipan, CNMI. The study area includes the
- entire inland watershed that contributes groundwater and surface water runoff to this
- approximately two-mile length of shoreline, as well as the adjacent offshore lagoon area
- extending out approximately 0.3 miles (Figure 1).

# 14 1.3 OVERVIEW OF THE PROPOSED ACTION

- 15 The Proposed Action involves the construction of a detention basin that would capture
- sediment, nutrients, and contaminants entrained in runoff waters before they enter the
- 17 lagoon. This would help improve the water quality of runoff waters into the lagoon,
- which in turn would help restore the degraded aquatic ecosystem structure within the
- 19 lagoon to a more natural state.

# **Alternatives Considered**

- 21 The alternatives analysis process was extensive, beginning with the overall consideration
- of three alternative detention basin sites and a variety of detention basin sizes at each site,
- to achieve the overall project goal of restoring the Saipan Lagoon aquatic ecosystem to a
- less degraded, more natural condition. Detention basins are temporary holding areas for
- stormwater that may also act as settling ponds for sediment transported by sheet flow.
- 26 The detention basins would be designed to capture first flush sediment and other
- 27 contaminants that enter the basins. The basins would include overflow systems that
- would route the water to the lagoon via pipe or drainage swale systems. Dual-purpose
- 29 type uses (soccer fields, parks, etc.) for the detention basins were originally considered,
- 30 but were found to be impractical. Three sizes of detention basin were designed and
- 31 considered for each of the three sites, corresponding to the expected influx of water
- during a two-year rainfall event, a five-year rainfall event, and a 10-year rainfall event.
- 33 The project alternatives were evaluated in terms of the cost to construct the different
- 34 detention basin sizes at each of the three sites, as well as the estimated amount of
- 35 environmental restoration that would occur in the lagoon as a result of the different
- project alternatives (Figure 2). The incremental cost analysis conducted in the Ecosystem
- Restoration Report (ERR) (Environet, 2013) concluded that the Cock Fight Arena site
- with a single two-year design basin is the most appropriate alternative, as it best meets
- 39 the purpose and need of the project by providing adequate lagoon restoration at a feasible
- 40 cost. In addition, a No Action alternative was evaluated. The three sites originally

- 1 considered for the detention basins, along with the proposed alternative basin designs at
- 2 the three sites are further described in Section 2 of this EA, and in detail in the ERR.

# 1.4 PURPOSE AND NEED

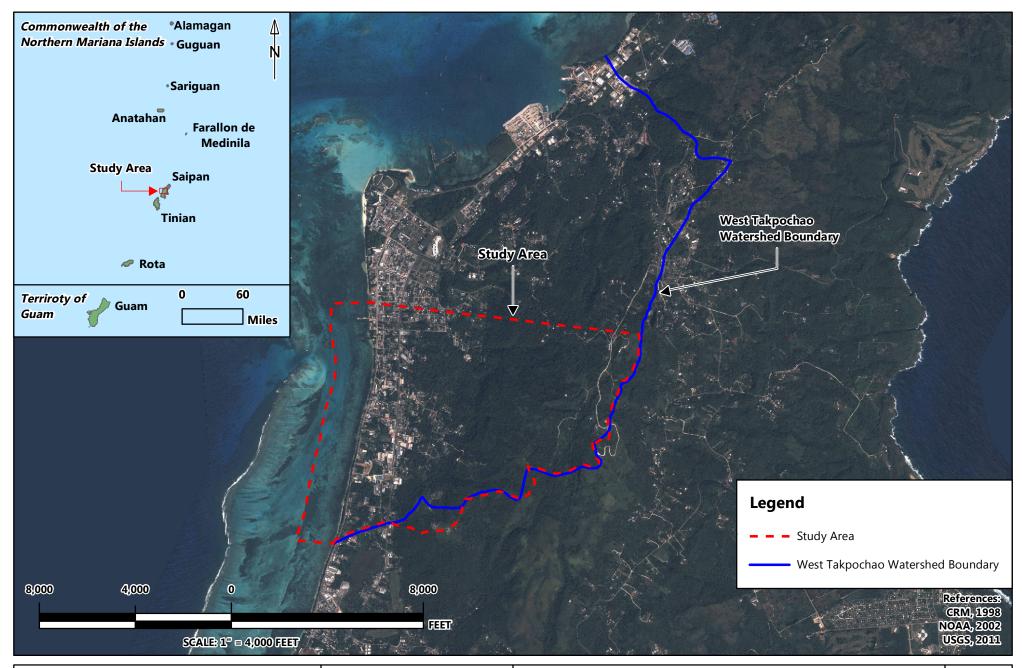

# 4 Purpose

3

- 5 The purpose of the Proposed Action is to determine an environmentally sensitive and
- 6 economically feasible means to improve the ecosystem function in the Saipan Lagoon by
- 7 reducing the amount of sediment, as well as other suspended solids that enter the lagoon
- 8 via stormwater runoff. A reduction of these constituents within the lagoon would help to
- 9 improve lagoon water quality, leading to an improvement of the degraded lagoon
- 10 ecosystem structure and function.
- 11 Indicators of this degradation include increased frequency of water quality standard
- 12 violations in near-shore recreational waters, changes in density, distribution and
- composition of sea grass communities in near-shore waters, high abundance of seasonal
- macro-algal growth, decrease in near-shore lagoon fish and degraded lagoon coral health.
- 15 The Proposed Action would provide the most appropriate environmental engineering
- solution to address the ongoing degradation of the water quality in the lagoon due to
- 17 unmitigated stormwater runoff. The Proposed Action would help meet the CNMI's
- interest in restoring the Saipan Lagoon's natural ecosystem function through capture of
- sediment and suspended solids in stormwater before entering coastal waters.

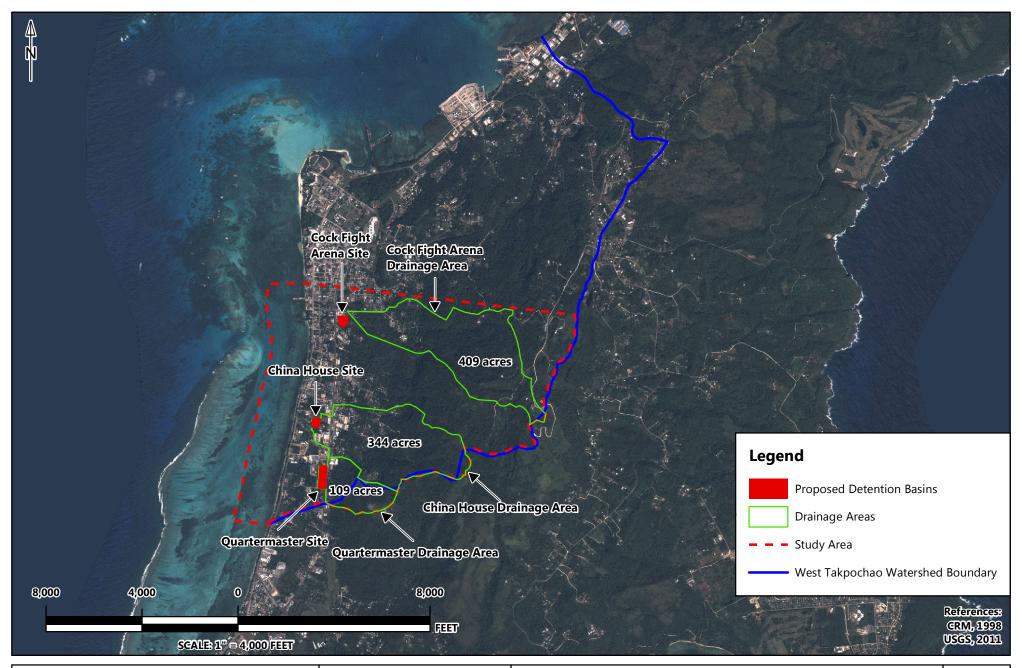

# 20 Need

- 21 A combination of increasing population and urbanization of the West Takpochao
- watershed over the past 70 years has led to degradation of the aquatic ecosystem that
- 23 makes up the Saipan Lagoon.
- 24 Degradation of ecosystem function in the Saipan Lagoon is a concern not only because of
- 25 the deterioration of natural resources supported by the lagoon, but also because
- degradation has progressed to the point that the aesthetic and recreational utility of the
- 27 lagoon has been adversely impacted. This is of substantial concern on Saipan because
- 28 the lagoon is a vital component of the tourism industry that accounts for the majority of
- 29 the local economy. Indicators of water quality degradation have been investigated and
- 30 presented in this EA and the ERR (Environet, 2013). These indicators will be discussed
- 31 briefly in the following sections, together with the desired outcomes of the future
- 32 restoration activity, and the best possible restoration alternative for the study area.

REVIEWED BY: MA	SAIPAN, CNMI	

#### 1.4.1 Sedimentation

- 2 Sedimentation is recognized as one of the most significant problems facing the Saipan
- 3 Lagoon and is a direct result of the urban development that has taken place within the
- 4 West Takpochao watershed. Reduction of the sediment load transported to the lagoon
- 5 would significantly improve the overall function of the aquatic ecosystem.
- 6 Sediment transport to lowland areas occurs naturally in Saipan. In the study area, the
- 7 amount of sediments being transported to the lagoon environment has increased in
- 8 conjunction with the spreading urbanization of the lowland areas within the watershed.
- 9 The increased number of roofs, roads, and other paved areas impervious to rain increases
- 10 the amount of runoff and tends to channel the runoff between properties. Construction
- 11 activities and clearing of the natural vegetation tend to disturb the natural soils rendering
- 12 them more susceptible to erosion. A decline in coverage by natural vegetation due to
- increased urbanization also limits the ability of the substrate to hold rainfall and makes
- these remaining lands more subject to runoff and erosion. The resulting increased levels
- of runoff and sedimentation to the lagoon overloads the ability of the natural seagrass
- 16 community to cope with these pollutants and can damage coral reefs and associated
- 17 ecosystems.
- Damage to coral reef ecosystems can result from direct sedimentation onto coral polyps
- or from increased nutrient concentrations that may lead to overgrowth by algae species.
- 20 A shift in reef species towards more nutrient tolerant and less diverse communities will
- 21 also lead to changes in the fish populations inhabiting the reef. In addition, less diverse
- 22 communities of coral are more susceptible to damage during natural disasters such as
- 23 typhoons. Further, any perceived decrease in the quality of the coral reef ecosystem is
- 24 likely to have adverse impacts on the Saipan tourism economy.
- 25 The Soil Conservation Service estimated erosion rates for Saipan soils present in the
- 26 Kagman Watershed on the eastern side of the island. The average erosion rate from the
- 27 forested upper watershed is estimated to be about three tons per acre per year while areas
- 28 under construction may exceed rates of 20 tons per acre per year. The developed
- 29 homestead area in Kagman, which is situated on a relatively flat limestone plateau, yields
- 30 between two to five tons of soil per acre per year.
- 31 Erosion rates for the soils present within the study area are not available. However,
- 32 initial observations made during the reconnaissance field visit of eroded gravel roads,
- 33 obvious sedimentation in storm drain gullies, and occasional lapses in implementation of
- 34 best management practice (BMP) regulations at construction sites suggest that erosion
- 35 rates may be high. An attempt to evaluate sedimentation rates within the study area was
- undertaken by studying deltaic deposits along the shoreline. Three sediment deltas were
- 37 surveyed five times at three different points from 2001 to 2002 during the wet and dry
- seasons in an effort to quantify sediment load entering the lagoon via stormwater runoff.
- The change in sediment delta volume throughout the study interval was notable. The
- 40 volume of sediment at each survey point fluctuated during the study. The total volume of
- sediment lost from the three deltas during the study interval was 478 cubic yards. This
- 42 sediment likely washed into the lagoon. Results of this study are discussed in detail in
- 43 the ERR (Environet, 2013).

### 1.4.2 Water Quality

- 2 Saipan has unique water issues that offer challenges to regulatory agencies such as the
- 3 CNMI Division of Environmental Quality (DEQ) and the CRMO. Finite freshwater
- 4 sources and impacts of urban development on surrounding marine environments are of
- 5 constant concern on an island such as Saipan. This section summarizes general water
- 6 characteristics on Saipan according to the CNMI DEQ Integrated 305(b) and 303(d)
- Water Quality Assessment Report, dated November, 2010.

#### 8 Groundwater

1

- 9 Two types of aguifers are dominant on Saipan; isolated limestone aguifers, as well as the
- more prevalent basal aquifer, which is the predominant source of freshwater on the
- 11 island. Due to the limited freshwater sources, the location and distribution of these
- aguifers is of extreme importance in the CNMI. Urban growth and an increase in
- population have led to several issues that threaten the freshwater aquifers. Increasing
- demand of freshwater has led to over-pumping of the basal lens aquifer, causing high
- 15 chloride levels due to saltwater intrusion.
- 16 Although most occurrences of groundwater contamination in Saipan have not been linked
- with a specific identifiable source, the highly suspected sources, in addition to saltwater
- intrusion, include the following:
- petroleum compounds from underground storage tanks;
- pesticides, halogenated solvents, petroleum compounds, nitrate, metals, bacteria, protozoa, and viruses from disposal activities at landfills;
- nitrate, bacteria, protozoa, and viruses from septic tanks as well as pipelines and sewer lines; and
  - halogenated solvents, petroleum compounds, and metals from small-scale manufacturing and repair shops.
- Point source and nonpoint source pollution due to heavy urbanization can also threaten ground water sources through infiltration of the study area's highly permeable top soils.

#### Surface Water

24

25

- 29 The CNMI has designated two classes of water (AA and A) for marine uses. Class AA
- represents high-quality waters that are considered to be in a "natural" and "pristine" state.
- 31 The CNMI Water Quality Standards states that "to the extent practicable, the wilderness
- 32 character of such areas shall be protected," and does not permit any discharge of
- 33 pollutants in class AA waters. Class A waters have been designated in two parts of
- 34 Saipan, and generally represent a slightly lower quality of water in which some
- discharges may be permitted, for example, the two sewage treatment plant outfalls on
- 36 Saipan. Nevertheless, Class A waters must support recreational use and the propagation
- of fish, shellfish, and wildlife, and strict water quality standards have been set for the
- 38 protection of these uses in Class A marine waters. Additionally, further protection is
- 39 afforded through the CNMI Anti-Degradation Policy, which is part of the Water Quality

- 1 Standards and protects existing uses and water quality in any waters, despite their
- 2 classification.
- 3 The majority of the coastal marine waters on Saipan are designated as Class AA,
- 4 including the study area. These waters should remain in their natural pristine state as
- 5 nearly as possible with an absolute minimum of pollution or alteration of water quality
- 6 from any human-related sources or actions. The uses protected in these waters are the
- 7 support and propagation of shellfish and other marine life, as well as the conservation of
- 8 coral reefs and wilderness areas, oceanographic research, and aesthetic enjoyment and
- 9 compatible recreation inclusive of whole body contact (e.g., swimming and snorkeling)
- and related activities.
- Both point and non point source pollution are responsible for lowering the quality of the
- 12 CNMI's surface waters. Sewage out-falls, sewer collection overflows, sedimentation
- 13 from unpaved roads and development, urban runoff, reverse osmosis discharges from
- 14 hotel treatment systems, and nutrients from agricultural areas and golf courses are the
- most significant contributors to the degradation of the CNMI's surface and marine water
- quality. Surface water quality is difficult to measure and properly assess due to the many
- variables that affect surface water, including rainfall events, tidal fluctuations, and other
- 18 atmospheric and oceanographic conditions.
- 19 The CNMI Marine Monitoring Team (MMT) was initially established in 1997 to aid in
- 20 understanding the current conditions of coral reefs and coral reef resources in the CNMI.
- 21 The MMT consists of members from the CMI DEQ, CRMO, and the CNMI Division of
- 22 Fish and Wildlife (DFW). It is the goal of the MMT to continue this long-term
- 23 monitoring program to continually assess reefs and aquatic resources of the CNMI.
- According to the CNMI MMT, in order to properly and accurately assess water quality, it
- 25 is best to couple both marine habitat health data with water quality measurements.
- 26 Decreased water quality threatens marine environments because coral reefs and other
- 27 marine systems rely on good water quality for proper function and prosperity.
- Monitoring and measuring water quality and the health of aquatic ecosystems is the most
- 29 efficient way to determine marine water quality.

#### 30 1.5 REGULATORY FRAMEWORK

- 31 In addressing environmental considerations, USACE is guided by several relevant
- 32 statutes and Executive Orders (EO) that establish standards and provide guidance on
- environmental and natural resource management and planning. These statutes and EO
- 34 include, but are not limited to, the Rivers and Harbors Act, the Coastal Zone
- 35 Management Act (CZMA), the Endangered Species Act (ESA), the Fish and Wildlife
- 36 Coordination Act, the Magnuson-Stevens Fishery Conservation and Management Act,
- 37 the National Historic Preservation Act (NHPA), the Resource Conservation and
- 38 Recovery Act (RCRA), EO 13089 (Protection of Coral Reefs), EO 12898 (Federal
- 39 Actions to Address Environmental Justice in Minority Populations and Low-Income
- 40 Populations), and EO 13045 (Protection of Children from Environmental Health Risks
- and Safety Risks). Key provisions of these statutes and EOs are discussed throughout
- subsequent sections of the EA, and in detail in Section 4 of this EA.

#### 1 1.6 PUBLIC INVOLVEMENT AND AGENCY CONSULTATION

- 2 Public participation is organized in the form of public posting (newspaper bulletins and
- 3 other accessible public media) and agency consultations.

# 4 1.6.1 Agency Scoping Meetings

- 5 A series of small meetings were held with different departments of the Saipan
- 6 Government from February to August 2002. A brief summary of attendees and topics of
- 7 discussion are contained in Appendix E. Another series of meetings were held with
- 8 several CNMI and U.S. federal governmental agencies in October, 2011. Representatives
- 9 from the following government agencies were briefed and consulted during the meetings:
- 10 CNMI CRMO
- CNMI DPW
- CNMI DEQ
- CNMI Department of Public Lands
- U.S. National Oceanic and Atmospheric Administration (NOAA)

### 15 **1.6.2** Legislative Meetings

- 16 Two meetings were conducted with the Saipan Legislature from June through August of
- 17 2002. The first meeting was held on June 27, 2002 to introduce the study to the local
- authorities and the local newspaper. The second meeting was held on August 15, 2002,
- 19 to brief legislators on the progress of the EA and to discuss issues on acquiring private
- 20 land for the proposed project. A third meeting was conducted with the CNMI Legislature
- 21 on October 25, 2011 in order to provide a study update and to consult the CNMI
- Legislative representatives. Another meeting with the project team and the Governor was
- 23 held at the Legislature on October 26, 2011 in order to provide updated study information
- and consult the Governor.

# 25 **1.6.3 Public Meetings**

- 26 Two articles were printed in the local newspapers on June 29 and July 1st of 2002. An
- 27 updated public scoping period will be initiated following publication of the Draft EA,
- 28 including a study update and call for public comments via the local newspaper.
- 29 Interested members of the public will be able to comment on the draft document and have
- their comments taken into consideration during preparation of the Final EA.

#### 1 2. DESCRIPTION OF THE PROPOSED ACTION AND ALTERNATIVES

- This section describes the alternatives, including the Preferred Alternative, that were developed to meet the following objectives:
  - Select an environmentally sensitive and economically feasible alternative that would restore the Saipan Lagoon aquatic ecosystem to be self-sustaining in its ecologically modified environment, by examining a range of alternative basin locations and sizes in the West Takpochao watershed. Evaluation criteria used include the amount of freshwater the basin could hold (capacity), the percent of the watershed that would drain into the basin, and the relative amount of sediment, hazardous runoff, and runoff loading the basin would receive compared to the amount produced within the study area, as well as the associated construction costs;
  - Construct the selected detention basin facility that meets the engineering and cost considerations;
    - Restore the lagoon environment to a more natural state following construction of the proposed detention basin(s).

# 2.1 ALTERNATIVES CONSIDERED BUT ELIMINATED FROM FURTHER ANALYSIS

- The following alternatives were considered during the initial alternative formulation process:
- 21 No Action

4

5

6 7

8

9

10

11 12

13

14

15

16

- Capturing and pumping contaminants offshore
- Erosion control
- Detention basins
- 25 The no action alternative was considered to be unresponsive to the needs of the local
- 26 sponsor and was eliminated from further evaluation. The no action alternative was,
- 27 however, included in the alternatives analysis in the ICA (concurrently being prepared
- with this report) as well as the EA as required by the Council of Environmental Quality
- 29 (CEQ) regulation 40 Code of Federal Regulations (CFR) Section 1502.14(d). Capturing
- 30 and pumping contaminants offshore was eliminated from further evaluation because
- 31 CNMI stated that they cannot afford to maintain the mechanical pumps. Erosion control
- within the upper portion of the watershed was considered but not carried forward for
- of the difference of the water that the control of the control of
- further evaluation since it was not considered to be sufficient in addressing the purpose
- 34 and need of the project. Construction of detention basins was considered the most cost
- 35 effective and efficient in addressing the purpose and need of the project; therefore, was
- 36 carried forward for further evaluation.
- 37 Three alternative detention basin sites (China House, Quartermaster, and Cock Fight
- 38 Arena), that are located in low-lying areas within the West Takpochao watershed, were
- 39 considered to achieve the overall project goal and evaluated in terms of the amount of

- 1 freshwater they could hold (capacity), the percent of the watershed that would drain into
- 2 the basin, and the relative amount of sediment, hazardous runoff, and runoff loading they
- 3 would receive compared to the amount produced within the entire study area. Three sizes
- 4 of detention basins were designed for each of the three sites, corresponding to the
- 5 expected influx of water during a two-year, five-year, and 10-year rainfall event. Each
- 6 detention basin was characterized in terms of its cost and expected benefits using the cost
- 7 effectiveness (CE)/incremental cost analysis (ICA) program.
- 8 Since the three sites currently flood during heavy rains, all three were determined to be
- 9 effective in receiving runoff waters and functioning as detention basin sites. Three storm
- events were evaluated, including two-year, five-year, and 10-year recurrence storms (all
- one-hour duration events). The watershed analysis for each storm event and site is
- included in the Preliminary Drainage Design for Aquatic Ecosystem Restoration Study,
- 13 Saipan Lagoon, Saipan, Northern Mariana Islands (Community Planning & Engineering,
- 14 Inc., 2012). This report is included as Appendix A.
- 15 The CE/ICA program developed by the USACE Institute for Water Resources was used
- 16 to conduct a CE/ICA for the different alternative sites and design combinations.
- 17 Economic analysis for environmental planning consists of two analytical processes that
- together form the CE/ICA. CE analysis identifies the least-cost alternative for each level
- of environmental output. Following the CE analysis, an ICA was performed to show the
- 20 incremental change in cost with increasing levels of environmental output. Including the
- 21 No Action alternative, 19 cost effective least-cost combinations of the three detention
- basin sites were subjected to an ICA in which only four combinations were retained for
- 23 the final incremental analysis (Environet, 2013). Each alternative consists of a different
- 24 combination of detention basins to be constructed in the West Takpochao watershed.
- 25 The dollar cost of each alternative, along with the lagoon habitat units (LGHUs) restored
- 26 for each alternative were key factors in evaluating the feasibility and effectiveness of
- each alternative considered for analysis. The LGHUs represent the equivalent acres of
- 28 lagoon area restored by implementing the chosen detention basin design combinations for
- 29 each alternative. The LGHUs are a derived variable based on acres of lagoon habitat
- 30 restored by reducing sediment, and contaminant runoff from potentially contaminating
- activities (PCAs). A PCA is defined as a facility or activity that 1) stores, transmits, uses,
- or produces contaminants, chemicals or by-products; and 2) has the potential to release
- contaminants that may impact the quality of the lagoon water (Environet, 2013).

#### **Alternative Sites Considered**

35 China House Site

- 36 The proposed China House site is located in the mid-southern portion of the study area
- 37 about halfway between Middle and Beach Roads, across from the Pizza Hut building and
- 38 Beach Road, near the China House restaurant (Figure 2). Topographically, the Site is
- 39 characterized by a natural drainage channel that flows to an outfall located along Beach
- 40 Road in the center of the proposed Site. The remaining Site area is predominantly flat to
- 41 slightly sloping toward Beach Road and the lagoon.

- 1 The Site currently serves as a natural drainage area for surface water from Middle Road
- 2 and the upper parts of the Gualo Rai area. Surface water reaches the lagoon through this
- 3 area via surface sheet flow and through the natural swale. There is currently a storm
- 4 water catch basin located along Middle Road adjacent to Pizza Hut that collects surface
- 5 water and diverts it beneath Middle Road and into the proposed detention basin Site.
- 6 During medium to large storm events, the catch basin is insufficient to handle the volume
- 7 of runoff and severe flooding occurs along Middle Road at the Pizza Hut location. The
- topographic nature of this site is conducive to the construction of a detention basin. 8

#### 9 Quartermaster Site

- 10 The proposed Quartermaster Site is located at the southern-most end of the study area, at
- 11 the intersection of Quartermaster Road to the south and Middle Road to the east
- 12 (Figure 2). The Site is currently vacant and overgrown, and generally slopes to the
- 13 southwest. Several commercial and residential buildings lie adjacent to the proposed
- 14 Site.
- 15 Quartermaster Road, together with adjacent swales, serves as a major drainage route for
- 16 surface water during rain events. A drainage culvert is located beneath Middle Road at
- 17 the intersection of Middle and Quartermaster Roads. The contributory area to surface
- 18 runoff in this area includes Middle Road and areas in the southern portion of the West
- 19 Takpochao watershed.
- 20 This area would be used in a similar manner as the China House site; a detention basin
- 21 that would act as a settling pond for sediment and contaminants prior to discharging
- 22 surface water to the lagoon.

#### 23 Cock Fight Arena Site

- 24 The proposed Cock Fight Arena Site is located on the east side of Middle Road at the
- 25 northern end of the study area (Figure 2). The closest cross street is Commonwealth
- 26 Road, located approximately 200 feet north of the Cock Fight Arena Site. This Site is
- 27 characterized by an abandoned quarry pit that occupies roughly one third of the Site, in
- 28 the southeastern corner. The depression of the pit extends approximately ten feet in
- 29 depth at its deepest point. The remaining portion of the Site is predominantly flat to
- 30 slightly sloping in the direction of the quarry depression. The Arena is currently located
- 31 on the western side of the Site. Commonwealth Road acts as a major channel for surface
- 32 runoff water from a large contributory area during medium to large flood events. During
- 33 rain events, surface water streams down Commonwealth Road and into storm drains
- 34 located at the intersection of Commonwealth and Middle Roads. The storm drain diverts
- 35 the water north toward Garapan and into a large surface water outfall that enters the
- 36
- lagoon near the Dai Ichi Hotel. The area of restoration for this alternative thus may
- 37 extend north of the study area indicated on Figure 2. The contributory area for surface
- 38 flow in this area includes many unpaved areas in the upper reaches of the watershed,
- 39 leading to large amounts of sediment transport from the upper reaches of the watershed to
- 40 the lagoon. During medium to large rain events, the current storm drain is insufficient to
- 41 handle the amount of flow that occurs, resulting in severe flooding at the intersection of
- 42 Commonwealth and Middle Road and the surrounding areas.

September 2013

#### **Alternative Basin Sizes Considered**

2 The numbering sequence for all combinations of alternatives follows the following format:

- Prefix C, Q, or A refers to the China House (C), Quartermaster (Q), or Arena site (A).
- Numeral 0, 1, 2, or 3 refers to the no action (0), two-year (1), five-year (2), or 10-year (3) design level, respectively. Thus C2 is the China House five-year design while Q0 refers to the Quartermaster no action alternative.

Based on the assumptions that any or all of the three sites could be developed concurrently at the no-build, two-year, five-year, or 10-year design level, there were 64 different plan combinations. After conceiving all possible plan combinations, inefficient combinations were eliminated by identifying combinations with identical levels of output and eliminating the one with the higher cost. This process resulted in the identification of 48 least-cost combinations.

The 48 least-cost combinations were then analyzed for CE by identifying and eliminating the combinations that produce a lower level of output for the same or greater cost than another combination. This CE analysis resulted in a set of 18 cost-effective combinations. The 18 cost-effective combinations were then subjected to a preliminary ICA in which combinations with the lowest incremental cost per output for a particular output level was identified. Seven best buy plans (i.e., the plan combinations with the lowest incremental cost per output level) were retained as a result of this preliminary ICA analysis.

Of the seven best buy plans, three combinations with the highest incremental cost were eliminated from further evaluation because the significantly higher cost of these three combinations were not justified by a significant increase in output. In addition, the no action combination, which was considered to be unresponsive to the needs of the local sponsor, was eliminated from further evaluation. Once the final three combinations were identified, they were subjected to an Abbreviated Cost and Schedule Risk Analysis, in which the contingencies were calculated for each alternative. Once the contingencies were calculated, they were placed in the Total Project Cost Summary to determine the total project cost for each alternative. The final ICA was performed on the three combinations using the total project cost instead of the estimated costs that were used for the preliminary ICA. Table 1 summarizes the findings of this alternatives analysis phase.

1

**Table 1: Summary of Possible Alternative Development Scenarios** 

ALTERNATIVE	Project	Size(s) of Detention	Comment
	Location(s)	Basin(s)/Storage Capacity	
No Action	none	none	No restoration of lagoon's natural state; continued environmental impact. Does not meet purpose and need.
Preferred Alternative (C0Q0A1)	Cock Fight Arena	two-yr design basin/11.85 ac-ft	Beneficial impact on the aquatic ecosystem of the lagoon at a feasible cost. Meets purpose and need.
Alternative 3 (C2Q0A1)	China House Cock Fight Arena	five-yr design basin/13.54 ac-ft two-yr design basin/11.85 ac-ft	Beneficial impact on two regions of the lagoon; developmental costs three times higher than the Preferred Alternative. Increase in cost not justified by level of output.
Alternative 4 (C2Q2A1)	China House Quartermaster Cock Fight Arena	five-yr design basin/13.54 ac-ft five-yr design basin/4.885 ac-ft two -yr design basin/11.85 ac-ft	Beneficial impact on three regions of the lagoon; much greater cost not justified by level of output. Therefore eliminated from further analysis.
Alternative 5 (C2Q3A1)	China House Quartermaster Cock Fight Arena	five-yr design basin/13.54 ac-ft ten-yr design basin/6.92 ac-ft two -yr design basin/11.85 ac-ft	Significantly higher costs not justified by significant increase in output. Therefore eliminated from further analysis.
Alternative 6 (C3Q3A1)	China House Quartermaster Cock Fight Arena	10-yr design basin/15.84 ac-ft 10-yr design basin/6.92 ac-ft 2-yr design basin/11.85 ac-ft	Significantly higher development costs not justified by significant increase in output. Therefore eliminated from further analysis.
Alternative 7 (C3Q3A3)	China House Quartermaster Cock Fight Arena	10-yr design basin/15.84 ac-ft 10-yr design basin/6.92 ac-ft 10-yr design basin/14.23 ac-ft	Significantly higher development costs not justified by significant increase in output. Therefore eliminated from further analysis.

2

4

5

6 7

8

As a result of the final ICA, one combination with the highest output but with the highest incremental cost was eliminated from further evaluation considering the relatively high cost per output that was not matched by its level of output. The remaining two combinations (C0 Q0 A1 and C2 Q0 A1) were retained for further evaluation and underwent a review of their potential benefits and costs. Table 2 summarizes the findings and rankings of the ICE.

September 2013

**Table 2: Final Incremental Cost Analysis** 

Combination	Average Annual Cost	Average Annual LGHUs (equivalent acres)	Average Annual Cost per LGHU	Incremental Annual Cost	Incremental Annual Output (equivalent acres)	Annual Incremental Cost per Output
C0 Q0 A1	\$300,375	4.22	\$71,182	\$300,375	4.22	\$71.18
C2 Q0 A1	\$458,532	8.82	\$51,991	\$158,157	4.60	\$34.38

- 2 Of the two combinations retained following the final ICA, it was determined that the
- 3 second alternative (C2 Q0 A1) was unaffordable, and as a result, the first alternative (C0
- 4 Q0 A1) was selected as the Preferred Alternative by the project sponsor (the CNMI
- 5 CRMO). A detailed analysis of costs associated with the alternatives can be found in the
- 6 ERR (Environet, 2013).

1

# 7 The Least Environmentally Damaging Practicable Alternative (LEDPA) Analysis

- 8 The project alternatives were analyzed to identify the LEDPA in accordance with 40 CFR
- 9 Part 230.10(a). Under these guidelines the USACE requires that the LEDPA is
- 10 considered for implementation as the Preferred Alternative.
- Alternatives five through seven would all offer adequate potential ecosystem restoration
- through improved water quality within the lagoon. However, these alternatives would
- require the commitment of costs that would not be practical to implement, given the
- projected output of environmental restoration for these alternatives. Therefore, one two-
- 15 year detention basin at the Cock Fight Arena site was chosen as the LEDPA, given its
- projected restoration area and feasible project cost (Table 1).

#### 17 2.2 PREFERRED ALTERNATIVE

- 18 The Preferred Alternative is the design and construction of a two-year detention basin at
- 19 the Cock Fight Arena Site (Figure 3). This scenario results in 70.33 LGHUs of total
- 20 restoration area in a distinct area of the lagoon. The total project cost of the Preferred
- 21 Alternative is estimated at 7.896 million dollars. A preliminary design of the required
- 22 improvements was completed for the Preferred Alternative.
- 23 Preliminary designs are discussed in greater detail in the Preliminary Drainage Design
- 24 Study (Appendix A). Local residents have indicated that during heavy rains, large
- amounts of sediment are washed away from sloped areas and deposited downstream.
- 26 Many roads and driveways are not paved and are severely damaged during moderate to
- 27 heavy rainfall events. It is anticipated from this information that large amounts of
- sediment may be deposited in the detention basins. For each detention basin design, the
- 29 outlet pipe is proposed to be wrapped in filter cloth and gravel, and to be located one to
- 30 three feet above the bottom of the detention basin. This will allow for sediment to settle
- 31 out in the basin and will require periodic removal of sediment from the basins.

#### 2.3 NO ACTION ALTERNATIVE

2 CEQ regulation 40 CFR Section 1502.14(d) requires an alternatives analysis to include the alternative of no action. Therefore, the No Action alternative will be analyzed in this 3 4 EA. The No Action alternative calls for no change to the existing infrastructure. No 5 detention basin will be constructed at any site and stormwater runoff will continue to 6 flow directly into the lagoon. The No Action alternative is presented in the EA in order to analyze the environmental conditions that would occur if the proposed detention basins 7 8 are not implemented within the study area. It also serves as the baseline for comparative 9 analysis of impacts.

Table 3 summarizes total project costs, benefits and environmental acceptability of the Preferred Alternative detention basin design versus the No Action Alternative. A detailed description and breakdown of the total project cost associated with the Preferred Alternative is included in the ERR (Environet, 2013).

1415

The EA is considering the Preferred Alternative and a discussion of the consequences of taking no action, and is limiting the range of alternatives to action and no action because there are no unresolved conflicts concerning alternative uses of available resources.

The primary considerations for USACE and CNMI in selection of a Preferred Alternative include the purpose and need for the project, environmental impacts of the project, and the overall costs required for development. The No Action alternative has fewer short term environmental impacts compared to the Preferred Alternative; however, the No Action alternative does not meet the purpose and need for the proposed project to allow for the restoration of the natural ecology of Saipan Lagoon.

•	DRAWN BY: CB	PREFERRED ALTERNATIVE	3
	REVIEWED BY: MA	SAIPAN, CNMI	

# 3. AFFECTED ENVIRONMENT, ENVIRONMENTAL CONSEQUENCES AND MITIGATION

# **3 Environmental Impacts**

- 4 The CEQ regulations (40 CFR 1508.7 and 1508.8) define the impacts and effects that
- 5 must be addressed and considered by Federal agencies in satisfying the requirements of
- 6 the NEPA process, which includes direct, indirect and cumulative impacts.

# 7 Impacts

1

2

- 8 **Direct Impacts**: are caused by the action and occur at the same time and place.
- 9 **Indirect Impacts**: are caused by the action and are later in time or farther removed in
- distance, but are still reasonably foreseeable. Indirect impacts may include growth
- inducing impacts and other impacts related to induced changes in the pattern of land use,
- 12 population density or growth rate, and related effects on air, water and other natural
- 13 systems, including ecosystems.
- 14 Impacts include ecological (such as the effects on natural resources and on the
- 15 components, structures, and functioning of affected ecosystems), aesthetic, historical,
- 16 cultural, economic, social, or health, whether direct, indirect, or cumulative. Impacts
- may also include those resulting from actions which may have both beneficial and
- detrimental effects, even if on balance the agency believes that the effect will be
- 19 beneficial (40 CFR 1508.8).

#### 20 Significance of Environmental Impacts

- 21 According to the CEQ regulations (40 CFR 1500-1508), the determination of a
- significant impact is a function of both context and intensity.
- 23 **Context**: This means that the significance of an action must be analyzed in several
- 24 contexts such as society as a whole (human, national), the affected region, the affected
- 25 interests, and the locality. Significance varies with the setting of the Proposed Action.
- For instance, in the case of a site-specific action, significance would usually depend upon
- 27 the effects in the locale rather than in the world as a whole. Both short- and long-term
- 28 effects are relevant.
- 29 **Intensity**: This refers to the severity of impact. Responsible officials must bear in mind
- 30 that more than one agency may make decisions about partial aspects of a major action.
- 31 The following should be considered in evaluating intensity:
- 1. Impacts that may be both beneficial and adverse. A significant impact may exist even if the Federal agency believes that on balance the effect will be beneficial.
- 2. The degree to which the Proposed Action affects public health or safety.
- 3. Unique characteristics of the geographic area such as proximity to historic or cultural resources, park lands, prime farmlands, wetlands, wild and scenic rivers, or ecologically critical areas.

- 4. The degree to which the effects on the quality of the human environment are likely to be highly controversial.
  - 5. The degree to which the possible effects on the human environment are highly uncertain or involve unique or unknown risks.
  - 6. The degree to which the action may establish a precedent for future actions with significant effects or represents a decision in principle about a future consideration.
  - 7. Whether the action is related to other actions with individually insignificant but cumulatively significant impacts. Significance exists if it is reasonable to anticipate a cumulatively significant impact on the environment. Significance cannot be avoided by terming an action temporary or by breaking it down into small component parts.
  - 8. The degree to which the action may adversely affect districts, sites, highways, structures, or objects listed in or eligible for listing in the National Register of Historic Places or may cause loss or destruction of significant scientific, cultural, or historical resources.
  - 9. The degree to which the action may adversely affect an endangered or threatened species or its habitat that has been determined to be critical under the Endangered Species Act of 1973.
  - 10. Whether the action threatens a violation of Federal, State, or local law or requirements imposed for the protection of the environment (40 CFR 1508.27).
- 22 To determine significance, the severity of the impact must be examined in terms of the
- 23 type, quality and sensitivity of the resource involved; the location of the proposed project;
- 24 the duration of the effect (short or long-term) and other consideration of context.
- 25 Significance of the impact will vary with the setting of the Proposed Action and the
- surrounding area (including residential, industrial, commercial, and natural sites).

# **27 Cumulative Impacts**

- 28 Cumulative impacts are the impacts on the environment which result from the
- 29 incremental impacts of the action when added to other past, present, and reasonably
- 30 foreseeable future actions regardless of what agency (Federal or non-Federal) or person
- 31 undertakes such other actions. Cumulative impacts can result from individually minor
- 32 but collectively significant actions taking place over a period of time.

#### 33 3.1 GEOLOGY AND SOILS

#### 34 3.1.1 Existing Conditions

#### 35 Geology

- 36 The island of Saipan is composed of a volcanic core upon which a series of discrete
- 37 limestone formations have been deposited by coral reefs when these sections of the island
- were below sea level. Roughly 90 percent (%) of the surface of the island is currently
- 39 mantled with limestone, with the remaining areas chiefly comprising volcanic outcrops
- and unconsolidated beach or marsh deposits (Figure 4). The aerial distribution of rock

	PROJECT NO.: 1057	PROJECT NO.: 1057	ENVIRONMENTAL ASSESSMENT	
-OF Environet In	<u> </u>	DATE: APRIL, 2013	SAIPAN LAGOON AQUATIC ECOSYSTEM RESTORATION STUDY	FIGURE
CILIVII ONEL, III	1C. D	DRAWN BY: CB	SURFACE GEOLOGY OF SAIPAN	4
•	R	REVIEWED BY: MA	SAIPAN, CNMI	

- type on the island has been created by successive episodes of tectonic uplift resulting
- 2 from the flexure of the outer edge of the Philippine Plate in response to subduction of the
- 3 Pacific Plate to the east of Saipan along the Marianas Trench (Karig, 1971). The thick
- 4 fringing limestone units, which are exposed at elevations of up to 1,540 feet above mean
- 5 sea level on the summit of Mount Takpochao, have become sub-aerially exposed as a
- 6 result of these tectonic processes.
- 7 The study area is situated in the western central part of the island of Saipan. The area
- 8 between the shoreline and Middle Road is a slightly to moderately sloping coastal plain
- 9 composed of unconsolidated limestone derived sediments. The area inland of Middle
- 10 Road possesses the characteristic geomorphology on the island of Saipan with slightly to
- moderately sloping topographic plateaus separated by seaward-facing scarps of emergent
- 12 limestone.
- 13 The western half of the island, where the site investigation was conducted, is bordered by
- a large barrier reef and lagoon. Cloud et al. (1956) show the Garapan coastal plain to be
- underlain by recently emerged lime sands that overlie competent limestone reef at
- 16 varying depths.

#### 17 **Soils**

- 18 The characteristics of the surface soils within the study area generally vary from the
- shoreline to upland areas of the watershed. The lowland areas that extend from the
- shoreline to directly inland of Middle Road are dominated by soils of the Chinen-Urban
- Land Map Unit (Young, 1989). These soils are highly porous and account for the lack of
- 22 natural streambeds or continuous drainage ways across the lowland areas. The areas
- 23 upland of Middle Road in the vicinity of Gualo Rai are covered by soils of the Kagman-
- 24 Saipan Map Unit while further inland the land area is dominated by the Takpochao-
- 25 Chinen-Rock Outcrop Map Unit. The Chinen-Urban Land Map unit in the lowlands
- between Middle Road and the Beach Road is the soil unit most prone to erosion in the
- 27 study area. However, the largest percentage of the sedimentation that occurs along the
- 28 Beach Road drainages appears to come from quarried limestone backfill used for road
- and lot surfacing, rather than from erosion of the underlying native soils.

#### 30 3.1.2 Potential Impacts and Mitigation

#### 31 No Action

- 32 Under the No Action alternative there would be no change to geology and soils within the
- 33 study area. Soils and sediment would continue to be eroded and deposited within the
- 34 lagoon by stormwater runoff, leading to cumulative impacts to the lagoon water quality
- 35 from soil erosion.

#### 36 Preferred Alternative

- 37 The Preferred Alternative would have less than significant impacts on affected soils
- within the study area during the construction period through the institution of appropriate
- 39 soil erosion control BMPs, such as use of silt fencing. Soils would be excavated in order
- 40 to construct the detention basin. The excavated soils would be reused or trucked to the

- 1 Marpi Landfill in Saipan for disposal. No significant impacts to geology and soils are
- 2 anticipated from the Preferred Alternative.

# 3 3.2 SOLID AND HAZARDOUS WASTE

- 4 The U.S. Environmental Protection Agency (EPA), under RCRA, regulates the
- 5 generation and disposal of solid and hazardous waste, as defined in 40 CFR Part 261,
- 6 Identification and Listing of Hazardous Waste. An integral part of the aquatic ecosystem
- 7 restoration study is to identify sources that contribute nutrients or contaminants to the
- 8 lagoon. PCAs that reside within the study area were inventoried and subjected to a
- 9 susceptibility analysis. The guideline utilized in the analysis is the Source Water
- 10 Assessment Program (SWAP) that was part of the Safe Drinking Water Act (SDWA)
- amendment in 1996. The SWAP was used to assess the susceptibility of all drinking
- water sources to activities that have significant potential to release contaminants to water
- 13 sources. Although drinking water is not the primary focus of this study, the same
- principles were applied during the assessment of PCAs that affect the lagoon water.
- 15 Therefore, for the purpose of this study, a PCA is defined as a facility or activity that 1)
- stores, transmits, uses, or produces contaminants, chemicals or by-products; and 2) has
- 17 the potential to release contaminants that may impact the quality of the lagoon water.
- Results of the study on water contaminants are discussed in greater detail in the ERR
- 19 (Environet, 2013).

## 20 **3.2.1 Existing Conditions**

- 21 The areas adjacent to Beach and Middle roads contain numerous commercial, residential
- and industrial facilities that are all potential sources of pollutants to surface and ground
- 23 waters which impact the lagoon. PCAs present in this area include gas stations,
- 24 automobile dealerships, septic systems associated with various residential and
- 25 commercial properties, and sediment erosion associated with construction and unpaved
- 26 roads. Additionally, the sewer collection system within the study area along Middle Road
- 27 is known to overflow, creating contamination from sanitary sewer overflows (SSOs). An
- inventory and map of PCAs in the study area are included in the ERR (Environet, 2013).

#### 29 **3.2.2 Potential Impacts and Mitigation**

- 30 No Action
- 31 Under the No Action alternative there would be no change to the existing environment.
- 32 Potentially hazardous materials from PCAs collected in stormwater runoff would
- 33 continue to impact the affected environment.
- 34 <u>Preferred Alternative</u>
- 35 Beneficial impacts are anticipated under The Preferred Alternative. The Preferred
- 36 Alternative would utilize detention basins to trap PCA runoff water prior to its transport
- 37 to the lagoon. With proper control and treatment, the runoff water will contain less
- 38 contaminants before entering the lagoon compared to the No Action alternative. The
- 39 Preferred Alternative would have insignificant impacts within the study area during the

- 1 construction period due to the use of construction equipment utilizing petroleum
- 2 products. The institution of construction BMPs, including frequent equipment and
- 3 vehicle inspections to assure proper function, would mitigate any releases of potentially
- 4 hazardous materials or petroleum products from construction equipment into the
- 5 environment.

#### 6 **3.3 NOISE**

- 7 Determination of noise levels are based on 1) sound pressure level generated (decibels
- 8 [dBA] scale), 2) distance of listener from source of noise, 3) attenuating and propagating
- 9 effects of the medium between the source and the listener, and 4) period of exposure.

# 10 **Regulatory Setting**

- 11 The average exterior noise level generally considered acceptable for projects receiving
- federal assistance is 65 day-night sound levels (DNL). The DNL represents the 24-hour
- average sound level for day, with nighttime noise levels increased by 10 dBA. The
- 14 CNMI does not have specific established noise level standards, and utilizes U.S. federal
- 15 noise level recommendations when necessary.
- 16 The EPA has identified a range of yearly DNL standards that are sufficient to protect
- public health and welfare from the effects of environmental noise (EPA, 1977). The EPA
- has established a goal to reduce exterior environmental noise to a DNL not exceeding 65
- 19 dBA and a future goal to further reduce exterior environmental noise to a DNL not
- 20 exceeding 55 dBA. Additionally, the EPA states that these goals are not intended as
- 21 regulations as it has no authority to regulate noise levels, but rather they are intended to
- be viewed as levels below which the general population will not be at risk from any of
- be viewed as levels below which the general population will not be at risk from a
- 23 the identified effects of noise.
- 24 The U.S. Occupational Safety and Health Administration (OSHA) has established
- 25 acceptable noise levels for workers. Table 4 shows permissible noise levels for varying
- 26 exposure times.

27 Table 4: OSHA Permissible Noise Exposures

Duration per day-hours	Sound level dBA slow response
8	90
6	92
4	95
3	97
2	100

0.25 or less	115

28 Source: OSHA, 2012

The Noise Control Act of 1972 (42 U.S.C. 4901 to 4918) establishes a national policy to promote an environment for all Americans free from noise that jeopardizes their health and welfare. To accomplish this, the Act establishes a means for the coordination of Federal research and activities in noise control, authorizes the establishment of Federal noise emissions standards for products distributed in commerce, and provides information to the public respecting the noise emission and noise reduction characteristics of such products (42 U.S.C. 4901). The Act authorizes and directs that Federal agencies, to the fullest extent consistent with their authority under Federal laws administered by them, carry out the programs within their control in such a manner as to further the policy declared in 42 U.S.C. 4901.

#### 3.3.1 Existing Conditions

The study area is located along a developed transportation corridor (Middle Road). The primary existing noise sources in the study area include traffic noise from Middle Road, as well as from other smaller feeder roads in the area. Other noise sources in the area include common noises from businesses along Middle Road, as well as residences in the area.

A-weighted sound level, measured in dBA is one measurement of noise. The human ear can perceive sound over a range of frequencies, which varies for individuals. In using the A-weighted scale for measurement, only the frequencies heard by most listeners are considered. This gives a more accurate representation of the perception of noise. Using this scale, the DNL of an urban/residential area, similar to conditions within the study area, can be estimated as approximately 70 dBA. Normal conversational speech at a distance of five to ten feet is approximately 70 dBA. The decibel scale is logarithmic, so, for example, sound at 90 dBA would be perceived to be twice as loud as sound at 80 dBA. Passenger vehicles, motorcycles, and trucks use the roads in the vicinity of the study area. Noise levels generated by vehicles vary based on a number of factors including vehicle type, speed, and level of maintenance. Intensity of noise is attenuated with distance. Some estimates of noise levels from vehicles are listed in Table 5 (Cavanaugh and Tocci 1998).

**Table 5: Typical Noise Sources** 

Source	Distance (feet)	Noise Level (dBA)
Auto, 40 mph	50	72
Automobile Horn	10	95
Light Auto Traffic	100	50
Truck, 40 mph	50	84
Heavy Truck or Motorcycle	25	90

31 Source: Cavanaugh and Tocci, 1998.

### 1 3.3.2 Potential Impacts and Mitigation

# 2 No Action

- 3 Under the No Action alternative no construction activities would occur in the study area,
- 4 therefore there would be no additional impacts to existing noise receptors within the
- 5 study area.

#### 6 Preferred Alternative

- 7 The Preferred Alternative would have less than significant impacts within the study area
- 8 from temporary noise impacts from construction equipment and vehicles during the
- 9 construction period. The institution of BMPs and properly scheduled work times would
- 10 further mitigate noise impacts. There would be no long term noise impacts associated
- with the operation of the proposed detention basin.

# 12 3.4 CLIMATE AND AIR QUALITY

#### 13 **Regulatory Background**

- 14 The CNMI utilizes the National Ambient Air Quality Standards (NAAQS) regulated by
- 15 the EPA to provide established sets of ambient air quality standards to protect human
- 16 health and welfare.
- 17 CNMI Administrative Code DEQ Chapter 65-10: Air Pollution Regulations establish
- standards to insure that air resources are protected against pollution and do not constitute
- a health hazard. Section 65-10-101 of the Code states that "a permit shall be required for
- 20 the construction and operation of all new sources or modifications of major sources of
- 21 emissions" (CNMI DEQ 65-10-101, p. 8).

#### 22 Climate Change

- 23 The impact of new development on climate has been a growing concern. Greenhouse
- 24 gases (GHGs) trap heat in the earth's atmosphere. Both naturally occurring and
- anthropogenic (man-made) GHGs include water vapor, carbon dioxide, methane, nitrous
- oxide, and ozone. According to guidance from the CEQ, during an analysis of direct
- effects, it is appropriate to: (1) quantify cumulative emissions over the life of the project;
- 28 (2) discuss measures to reduce GHG emissions, including consideration of reasonable
- 29 alternatives; and (3) qualitatively discuss the link between such GHG emissions and
- 30 climate change. However, it is not currently useful for the NEPA analysis to attempt to
- 31 link specific climatological changes, or the environmental impacts thereof, to the
- 32 particular project or emissions, as such direct linkage is difficult to isolate and to
- understand. The estimated level of GHG emissions can serve as a reasonable proxy for
- 34 assessing potential climate change impacts, and provide decision makers and the public
- with useful information for a reasoned choice among alternatives (CEO, 2010).
- 36 EC 1165-2-212 seeks discussion related to how Climate Change may mean continued or
- 37 accelerated global warming for the 21st Century which may contribute to
- continued or accelerated rise in global mean sea-level.

### 1 **3.4.1** Existing Conditions

- 2 The climate in Saipan is warm and humid throughout the year and is classified as tropical
- 3 marine, with an average temperature of 75 to 80 degrees Fahrenheit (Vander Brug, 1985).
- 4 Rainfall in the study area is seasonal and averages about 75 to 80 inches per year. The
- 5 wet season usually extends from July through November, followed by a dry season from
- 6 December through June. Saipan experienced drought-like conditions during 1998, when
- 7 the rainfall between January and November totaled roughly 41 inches, or roughly half the
- 8 annual mean.
- 9 The dominant winds in the Northern Marianas are trade winds, which blow from the east
- 10 or northeast. These winds are strongest and most constant during the dry season, when
- wind speeds of 15 to 25 miles per hour are common. During the rainy season, the trade
- winds often cease, and on some days the weather may be dominated by westerly moving
- 13 storm systems that bring heavy showers or steady, at times torrential, rains. These
- episodic, heavy rainfall events contribute the majority of the sediment and surface water
- 15 runoff that reaches the nearshore lagoon environment. Some of these heavy rainfall
- 16 events occur during typhoons.
- 17 According to the EPA, "the air quality in American Samoa, Guam, and CNMI is
- generally pristine, due to the wet climate, strong prevailing winds, and distance from any
- 19 pollution sources" (EPA, 2006). The air quality within the study area was reported as
- 20 generally good in a November, 2003 letter from the CRMO (Appendix D).

# 21 **3.4.2 Potential Impacts and Mitigation**

- 22 No Action
- 23 Under the No Action alternative there would be no additional impact to air quality within
- the study area.
- 25 Preferred Alternative
- 26 The Preferred Alternative would have less than significant impacts to air quality during
- 27 construction activities (i.e., fugitive dust emissions and GHG emissions from motorized
- 28 equipment exhaust). Potential impacts would be mitigated by utilizing BMPs during the
- 29 construction process, including proper maintenance and function of construction
- 30 equipment. There would be no long term impacts to air quality from the operation of the
- 31 proposed detention basin.
- 32 Additionally, there is no indication that sea level rise or ocean acidification would
- 33 impact the preferred action. The basin would be far above the existing shoreline and
- 34 therefore would not contribute to acidification because it would detain sediment from
- 35 entering the lagoon.

#### 36 3.5 HYDROLOGY AND WATER QUALITY

- 37 The watershed within the study area is predominately underlain by the Mariana
- 38 Limestone unit. This limestone unit is composed mostly of finely to coarsely
- fragmented, commonly coralliferous, algal, and, in part, clayey limestone (Cloud et al.,
- 40 1956). The Mariana Limestone typically is white to gray colored, moderately to

- 1 cavernously porous, and non-bedded to indistinctly bedded. In the coastal portions of the
- 2 study area, the land surface is typically covered by recent alluvium derived from erosion
- 3 of the upland limestone areas.
- 4 Residents of the island of Saipan are almost entirely dependent on groundwater as a
- 5 drinking water source. Historically, limited amounts of generally brackish water have
- 6 been exploited by dug wells along the coastal portion of the watershed. Potable water is
- 7 extracted from deep wells (the Gualo Rai well field) located in the inland portions of the
- 8 watershed.

9

#### Regulatory Background

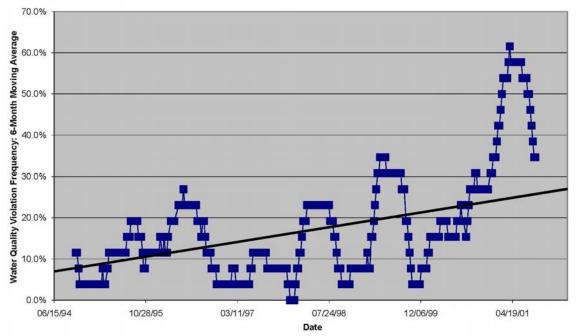

- 10 The CNMI has designated two classes of water (AA and A) for marine uses. Class AA
- represents high-quality waters that are considered to be in a "natural" and "pristine" state.
- 12 The CNMI Water Quality Standards states that "to the extent practicable, the wilderness
- 13 character of such areas shall be protected," and does not permit any discharge of
- pollutants in Class AA waters. Class A waters have been designated in two parts of
- Saipan, and generally represent a slightly lower quality of water in which some
- discharges may be permitted, for example, the two sewage treatment plant outfalls on
- Saipan. Nevertheless, Class A waters must support recreational use and the propagation
- of fish, shellfish, and wildlife, and strict water quality standards have been set for the
- 19 protection of these uses in Class A marine waters. Additionally, further protection is
- protection of these uses in class A marine waters. Additionally, future protection is
- afforded through the CNMI Anti-Degradation Policy, which is part of the Water Quality
- 21 Standards and protects existing uses and water quality in any waters, despite their
- 22 classification.

### 23 **3.5.1** Existing Conditions

#### 24 Surface Water

- 25 The lagoon water within the study area is designated as Class AA waters. However,
- 26 beach closures due to high levels of microbiological contamination are becoming
- 27 increasingly frequent along the west coast of Saipan. An interpretation of water quality
- 28 data collected by CNMI DEQ over an eight-year period indicates that there is a
- 29 significant trend of increasing microbiological contamination (enterococci bacteria)
- detections exceeding water quality standards. Figure 5 shows the increasing incidence of
- 31 water quality violations at Garapan Fishing Dock located at the northern end of the study
- 32 area.

Figure 5: Water Quality Violation Frequency at Garapan Fishing Dock, 1994-2002

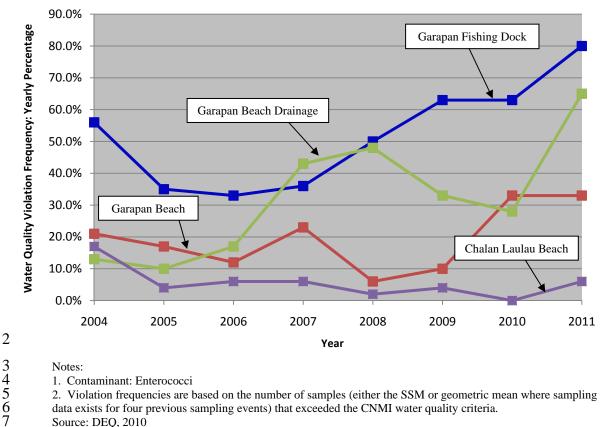

Source: DEQ, 2010

This increase in bacteriological contamination is a direct result of an increase in non point source pollution associated with urbanization and population growth. Non-point source contamination occurs predominantly from surface runoff and sediments transported by runoff, solid and human waste disposal, and agricultural activities.

Water quality data from 38 fixed stations along Saipan's most commonly used west coast beaches collected during more recent years by the CNMI DEQ indicate that sampling sites within the West Takpochau (Central) Watershed continue to consistently experience a significant number of water quality violations, leading to multiple "impaired" (violation frequency exceeds 10 %) or "significantly impaired" (violation frequency exceeds 25 %) listings (DEQ, 2010). Beach advisories notifying the public that the beach waters within 300 feet of the sampling point are not safe for swimming are triggered when either the single sample maximum (SSM) or geometric mean for the most recent four sampling events exceeds the CNMI water quality criteria. Figure 6 shows the yearly percentage of water quality violations from 2004 to 2011 at four of the CNMI DEQ sampling stations that fall within the study area. Three stations (Garapan Fishing Dock, Garapan Beach, and Garapan Beach Drainage) occur at the northern end of the study area whereas Chalan Laulau Beach occurs within the southern portion of the study area.

26

27

1. Contaminant: Enterococci

2. Violation frequencies are based on the number of samples (either the SSM or geometric mean where sampling data exists for four previous sampling events) that exceeded the CNMI water quality criteria. Source: DEQ, 2010

Water quality violation frequency over the past eight years at the three stations located at the northern end of the study area show an overall increasing trend, which is likely due to the more densely populated and urbanized areas within the northern part of the study area. On the other hand, water quality violations at Chalan Laulau Beach in the West Takpochao (South) Watershed, where less population and urbanization is observed, peaked in 2004 at 17%, and have subsequently decreased to 0-6%. The CNMI has proposed to delist the West Takpochao (South) segment from the impaired listing due to enterococci contamination because of the improvement in water quality within this segment. However, listing of the CNMI waters specific to aquatic life lists the West Takpochau (South) watershed as impaired, total maximum daily load (TMDL) required, and medium priority. The impaired listing is attributable to dissolved oxygen (DO), biocriteria, and orthosphosphate from sanitary sewer overflows, urban runoff, and sedimentation. The West Takpochau (Central) Watershed is listed as impaired, TMDL required, and high priority. The impaired listing is specific to aquatic life, fish consumption, and recreation due to enterococci, mercury, DO, biocriteria, and orthophosphate from sanitary sewer overflows, urban runoff, and sedimentation (DEO, 2010). Water quality data collected within the study area as well as the impairing listings of the watershed area that falls within the study area indicate that degradation of the water quality within the lagoon due to anthropogenic activities on land remain an issue and continued close monitoring of the lagoon water quality is necessary.

#### Groundwater

1

- 2 Groundwater in the western portion of Saipan occurs as an unconfined fresh to brackish
- 3 water lens that overlies saltwater. The top of the aquifer is thus bound by the water table
- 4 surface. Groundwater flows at a moderate gradient towards the ocean, becoming more
- 5 brackish near the ocean. The base of the aquifer in the inland portions of the watershed
- 6 is the westward plunging contact between volcanic basement and overlying coralline
- 7 deposits. The depth to the volcanic basement in the coastal portions of the study area is
- 8 unknown. The regional aquifer at the subject site is made up of the coral and
- 9 coral-derived material of the Marianas Formation. Due to the high permeability of this
- 10 limestone unit, the water levels within this aquifer fluctuate with ocean tides.
- 11 Two types of aquifers are dominant on Saipan, isolated limestone aquifers and the more
- prevalent basal aquifer, the predominant source of freshwater on the island. Due to the
- 13 limited freshwater sources, the location and distribution of these aguifers is of extreme
- importance in the CNMI. Urban growth and an increase in population have led to several
- issues that threaten the freshwater aguifers. Increasing demand of freshwater has led to
- over-pumping of the basal lens aquifer, causing high chloride levels due to saltwater
- intrusion. Point source and nonpoint-source pollution due to heavy urbanization can also
- threaten ground water sources through infiltration of the study area's highly permeable
- 19 top soils.

### 20 **3.5.2 Potential Impacts and Mitigation**

#### 21 No Action

- 22 Under the No Action alternative there would be significant cumulative impacts to the
- 23 lagoon water quality. Sediment, nutrients and other pollutants entrained in stormwater
- 24 would continue to flow into the lagoon. As a result, the lagoon water quality could
- continue to fall below water quality standards set by the CNMI.

#### 26 Preferred Alternative

- 27 The Preferred Alternative would result in beneficial impacts to the lagoon water quality
- 28 since sediment and other suspended solids would be filtered from the stormwater at the
- 29 proposed detention basin site. The Preferred Alternative would beneficially impact 70.33
- 30 LGHUs within the lagoon.

#### 31 3.6 TRAFFIC AND CIRCULATION

- 32 Vehicular traffic data was supplied by traffic count reports from the CNMI DPW
- 33 conducted in 2007. Several intersections were chosen within the study area for 24-hour
- 34 monitoring sessions. The traffic data supplied by the CNMI DPW is included in
- 35 Appendix B.

#### 36 **3.6.1** Existing Conditions

- 37 Beach Road and Middle Road are the primary transportation corridors on the western
- 38 coast of the island. They run north and south along the coast and are main thoroughfares
- 39 for the urbanized areas along the low land coastal area. Within the study area boundaries,

- 1 Gualo Rai Road and Quartermaster Road run perpendicular east and west. The results of
- 2 the 2007 CNMI DPW traffic count report at key intersections affecting the study area are
- 3 shown in Table 6. Peak a.m. traffic within the study area roadway network ranges from
- 4 106 to 846 cars per hour. Peak p.m. traffic within the study area roadway network ranges
- 5 from 132 to 991 cars per hour.

6

**Table 6: Traffic Count Survey** 

Monitoring Location	Weekly a.m. peak traffic count (time)	Weekly p.m. peak traffic count (time)	Average a.m. traffic counts (7:00-11:00)	Average p.m. traffic counts (12:00-17:00)
Middle Road South of Navy Road	649 (7:00)	664 (13:00)	368.50	352.08
Beach Road South of Micro Beach	344 (11:00)	400 (17:00)	259.08	256.56
Quartermaster Road between Beach and Middle Road	106 (7:00)	132 (14:00)	35.18	51.44
Beach Road north of Quartermaster Road	548 (11:00)	784 (17:00)	300.33	442.78
Middle Road north of Quartermaster Road	846 (11:00)	991 (14:00)	450.58	609.36
Middle Road south of Sugar King Road	686 (11:00)	768 (13:00)	418.40	506.32

### 7 3.6.2 Potential Impacts and Mitigation

#### 8 No Action

- 9 Under the No Action alternative no significant impacts to traffic are anticipated since the
- 10 existing site conditions would remain unchanged.

#### 11 Preferred Alternative

- 12 The Preferred Alternative would result in less than significant traffic circulation impacts
- that would occur during the construction phase from additional vehicle trips to and from
- 14 the proposed detention basin site via the local roadway network. These impacts would be
- 15 mitigated to a level of insignificance by proper forward planning utilizing BMPs,
- including a traffic control plan to be approved by the CNMI DPW before commencement
- of work. With these mitigation measures in place, impacts to the existing roadway
- 18 network would be less than significant.

#### 1 3.7 BIOLOGICAL RESOURCES

- 2 The U.S. Fish and Wildlife Coordination Act (FWCA) requires all Federal agencies to
- 3 consult with and give strong consideration to the views of the U.S. Fish and Wildlife
- 4 Service (USFWS), the National Marine Fisheries Service (NMFS), and State wildlife
- 5 agencies regarding the fish and wildlife impacts of projects that propose to impound,
- 6 divert, channel, or otherwise alter a body of water. USACE initiated consultation with
- 7 USFWS and NMFS in August 2003 and continued in October 2011. Copies of
- 8 correspondence are included in Appendix D. Resource agencies indicated that no critical
- 9 habitat are designated or proposed in the project area, and no candidate species are
- 10 known to exist in the Saipan area.

#### 11 3.7.1 Existing Conditions

- 12 The terrestrial habitat within and adjacent to the study area is dominated by urban
- landscaping and bird species. Other than birds, there are few terrestrial animals, such as
- 14 the introduced marine toads (*Bufo marinus*), African land snails (*Achatina fulica*), and
- domesticated farm animals in Saipan. Of the abundant avifaunal species monitored on
- the island, there tends to be a negative correlation between the density of native species
- and urbanization. Highly urbanized areas retain more exotic species.
- 18 The Saipan Lagoon nearshore environment is generally composed of a sand and
- sand/silt/rubble substrate covered by thick stands of seagrass and algae with only an
- 20 occasional coral head or limestone outcropping. Heavy input of freshwater (groundwater
- 21 and surface water runoff) into the nearshore environment is conducive to dense beds of
- large bladed, tall (up to three feet) seagrass (*Enhalus acoroides*) which are found in a 10
- 23 to 50 meter-wide band along the shoreline. Freshwater and nutrients are known to
- 24 enhance the growth of *Enhalus*, but excessive nutrients are believed to promote abundant
- 25 macro-algal growth that can have an adverse impact on corals and the function of the
- 26 marine ecosystem. Intermixed between stands of *Enhalus* and extended further out into
- 27 the lagoon, often to the reef, is the very common short seagrass Halodule uninervis,
- 28 which covers 20 to 70% of the benthic substrate in the lagoon between the Enhalus beds
- and the coral reef. Macroalgae species are abundant (especially near-shore) including
- 30 Halimeda, Padina, Caulerpa, Laurencia, Acanthophora and Dictyota as the most
- 31 common genera. In areas of high nutrient influx, such as the northern end of the study
- 32 area near Garapan, two types of rapid growth macroalgae are dominant; Enteromorpha
- 33 and Cladophora. The green, hair-like Enteromorpha and the pale hair-like Cladophora
- 34 have become nuisance algae because of their undesirable appearance and abundance
- along beaches and in the near-shore lagoon that are used for tourist activities.
- 36 Corals in the inshore zone are very sparse and are characterized by scattered, small
- 37 colonies of *Porites lutea* and *Pocillopora damicornis*. Live coral cover is less than one %
- overall, but some areas may support colonies of *Porites* and *Pocillopora* at densities up to
- 39 five percent. Invertebrates present in the inshore zone include the common sea cucumber
- 40 genera Holothuria, Actinopyga, and Bohadschia, the large starfish Linckia laevigata, and
- 41 the clam known locally as "Amsum". Lagoon fish resources include rabbitfish (Siganus),
- 42 mullet (Mugilidae), goatfish (Mullidae), snappers (Lutjanidae), the emperor fish
- 43 (*Lethrinus harak*), and silversides (Atherinidae).

- 1 Juveniles of many species may be found in the seagrass beds and occasional predatory
- 2 species such as groupers, jacks and barracuda may also be present. This resource is
- 3 utilized by local fishermen for subsistence and sport. It is of common opinion that the
- 4 inshore fisheries are in decline, and information from the CNMI DLNR supports this
- 5 contention (DLNR, 1998). Specific habitat units have been identified and delineated by
- 6 the MMT. Additionally, fish surveys conducted by the University of Guam revealed a
- 7 major decline in abundance of some of the major food fish groups between 1979 and
- 8 1996 in Saipan Lagoon (Starmer et al., 2008).
- 9 An island-wide market survey in 2009 documented the continued decline of nearshore
- fisheries (Houk, 2010). Initial consultation with NOAA staff indicated that no designated
- critical habitats for terrestrial species are listed in the study area. Further consultation
- was conducted with the CNMI DLNR, DFW in October, 2011. The CNMI DLNR DFW
- responded to consultation in October, 2011 in a letter with a list of species of concern for
- 14 the CNMI. The letter stated that a biological survey would be completed during the
- 15 construction permitting process in order to identify any species of concern within the
- 16 study area (Appendix D).
- 17 The following marine mammals under the protection of the Marine Mammal Protection
- 18 Act that have been identified in the region (NOAA, 2012):
- Bryde's whale (*Balaenoptera edent*);
- Cuvier's beaked whale (*Ziphius cavirostris*);
- Pygmy sperm whale (*Kogia breviceps*);
- Melon-headed whale (*Peponocephala electra*);
- Pygmy killer whale (*Pseudorea crassidens*);
- Killer whale (*Oreinus orea*);
- Short finned pilot whale (*Globicephaia macrorhynchus*);
- Spinner dolphin (*Stenella longirostris*);
- Striped dolphin (Stenella coeruleoalba);
- Pantropical spotted dolphin (*Stenella attenuate*);
- Common dolphin (*Delphinus delphis*); and
- Risso's dolphin (*Grampus griseus*)
- 31 Listed species under the National Marine Fisheries Service do not have designated
- 32 critical habitats in Saipan. Identified aquatic endangered species in the CNMI include the
- 33 Green Sea Turtle and the Hawksbill Sea Turtle (USFWS, 2011). Further, several coral
- 34 species known to exist within the Saipan lagoon are being considered for addition to the
- 35 threatened or endangered species list by NOAA (NOAA, 2012).
- 36 CNMI DFW indicates that several species of concern and federally listed endangered
- 37 species exist in the CNMI. However, none of the listed species habitats are known to

- 1 exist within the study area. The following species were identified in a letter from CNMI
- 2 DFW (October, 2011):
- Nightingale Reed Warbler (Acrocephalus luscinia);
- Mariana Common Moorhen (Gallinula chloropus guami);
- Micronesian Megapode (megapodius laperouse);
- Mariana Fruit Bat (*Pteropus mariannus*);
- Mariana Swiftlet (Aerodrames bartschi);
- 8 Rota Bridled White-eye (*Zosterops rotensis*); and
- Mariana Crow (Corvus kubaryi)
- 10 Listed species under the National Marine Fisheries Service do not have designated
- 11 critical habitats in Saipan.

# 12 3.7.2 Potential Impacts and Mitigation

- 13 No Action
- 14 Under the No Action alternative there would be cumulative impacts to lagoon habitats
- 15 from the continued uncontrolled runoff from the study area. There would be no controls
- 16 implemented to address the degraded ecosystem within the lagoon. Biological resources
- within the lagoon would continue to be impacted from sedimentation and other pollutants
- 18 suspended in runoff waters.

#### 19 Preferred Alternative

- 20 Subsection 2(h) of FWCA-Exempt Project Activities. FWCA exempts surface water
- 21 impoundments less than 10 acres. "The provisions of the Act shall not be applicable
- 22 to...projects for the impoundment of water where the maximum surface area...is less than
- 23 10 acres" (Water Resources Development Under the Fish and Wildlife Coordination Act,
- 24 November 2004).
- 25 The proposed action does not include work in streams nor any body of waters;
- 26 channelization; diversion of streams or storm drains etc. All work shall be done on urban
- 27 land determined to be absent of fish and wildlife. However, USACE conducted
- 28 consultation with USFWS and NMFS in an effort to consider the range of alternatives as
- 29 part of the ecosystem restoration project.

#### 30 Terrestrial and Aquatic Biological Resources

- 31 Due to the apparent absence of threatened or endangered species, critical habitat or
- 32 candidate species in the project area, no mitigation measures are proposed. There would
- 33 be indirect beneficial impacts to aquatic biological resources within the Saipan lagoon
- 34 under the Preferred Alternative. The proposed detention basin would help to reduce
- 35 sediment runoff into the lagoon, improving the water quality. Improved water quality
- would help to restore degraded lagoon habitats.

September 2013

#### 1 3.8 HISTORICAL AND CULTURAL RESOURCES

# 2 **3.8.1** Existing Conditions

- 3 Section 106 of the NHPA consultation conducted February 18, 2003 and October 30,
- 4 2012 with the CNMI Department of Community and Cultural Affairs indicated that the
- 5 Cock Fight Arena site consisted of an abandoned modern-day quarry prior to its current
- 6 use. A two person USACE, Honolulu District (USACE POH) pedestrian reconnaissance
- 7 level survey was conducted at a 10 meter transect spacing of the entire area of potential
- 8 effect in August, 2003. No cultural resources were located. Based on the 2003 survey of
- 9 the study area and research conducted, the Cock Fight Arena site has a low probability
- 10 for having historical or archeological resources. The reconnaissance level surface survey
- of the area identified no archaeological or cultural resources, as documented in the staff
- 12 archaeologist's project file in the Environmental Programs Branch, USACE, Honolulu
- 13 District, Fort Shafter, Hawaii.

14

- 15 Background research, consultation with CNMI Historic Preservation Office (HPO), and a
- 16 pedestrian two-person reconnaissance level survey helped conclude that the Cockfight
- 17 Arena site is a low probability area for historical or archaeological resources (refer to
- 18 letters in Appendix D). USACE has determined that the undertaking will result in no
- 19 historic properties affected as indicated in its letter to CNMI HPO dated October 30,
- 20 2012. Copies of all correspondence documenting the Section 106 consultation conducted
- are included in Appendix D.

# 22 3.8.2 Potential Impacts and Mitigation

- 23 No Action
- 24 Under the No Action alternative there would be no disturbance to the proposed project
- area, therefore there would be no change to the existing environment. There would be no
- 26 impacts to historical or cultural resources.
- 27 Preferred Alternative
- 28 The Preferred Alternative would have no adverse effect to historic properties. However,
- 29 prior to the start of any ground breaking construction activities associated with this
- 30 project, an AMP shall be completed by a qualified archaeologist and submitted to the
- 31 CNMI HPO for review and comments before its finalization prior to groundbreaking
- 32 activities. Further, monitoring by a qualified archeologist is recommended for any
- activities to ensure proper treatment of any possible subsurface historical,
- 34 cultural and/or archeological resources encountered. A full archaeological report
- 35 documenting the results of the archaeological monitoring activities shall also be
- 36 submitted at the end of all construction activities to the CNMI HPO for the agency's
- 37 library and files. Based on USACE POH Archaeological evaluation of the project area, it
- is concluded that the presence of a qualified archaeologist during construction will ensure
- 39 the protection of potentially significant cultural resources including human burial remains
- 40 that may be present subsurface within the project's area of potential effect. USACE POH
- 41 has concluded that with the presence of a qualified archaeologist monitor during all new
- 42 ground breaking construction activities as well as the submittal of a final AMP and post-

- 1 monitoring archaeological report to CNMI HPO, a determination can be made that the
- 2 Preferred Alternative shall have no adverse effect to historic properties.

# **3 3.9 LAND USE**

#### 4 3.9.1 Existing Conditions

- 5 The study area is located just south of the urbanized area of Garapan, and is characterized
- 6 as medium density in the north and low density within the southern portion of the study
- 7 area (Figure 7). The proposed detention basin site is zoned Mixed Commercial and
- 8 Rural. The Mixed Commercial "district provides for a broad spectrum of commercial
- 9 development that requires a moderate to high level of vehicular access and for low to
- moderate density residential development" (CNMI, 2008). The primary purpose of Rural
- lands is to "maintain rural character and control development sprawl" (CNMI, 2008).
- 12 The detention basin site is located within an urbanized strip of land located adjacent to
- 13 Middle Road. Development in this area consists of light industrial, commercial, retail
- and residential uses. The Gualo Rai residential area lies upslope and inland of Middle
- Road. Many of the small side roads and lots are unpaved. There are stormwater drains
- 16 along Middle Road and Beach Road, but there is no comprehensive collection and
- 17 conveyance system designed to control storm water within the developed areas in the
- 18 Guala Rai district and between Middle and Beach Roads.

# 19 **3.9.2 Potential Impacts and Mitigation**

### 20 No Action

21

2425

26

32

33

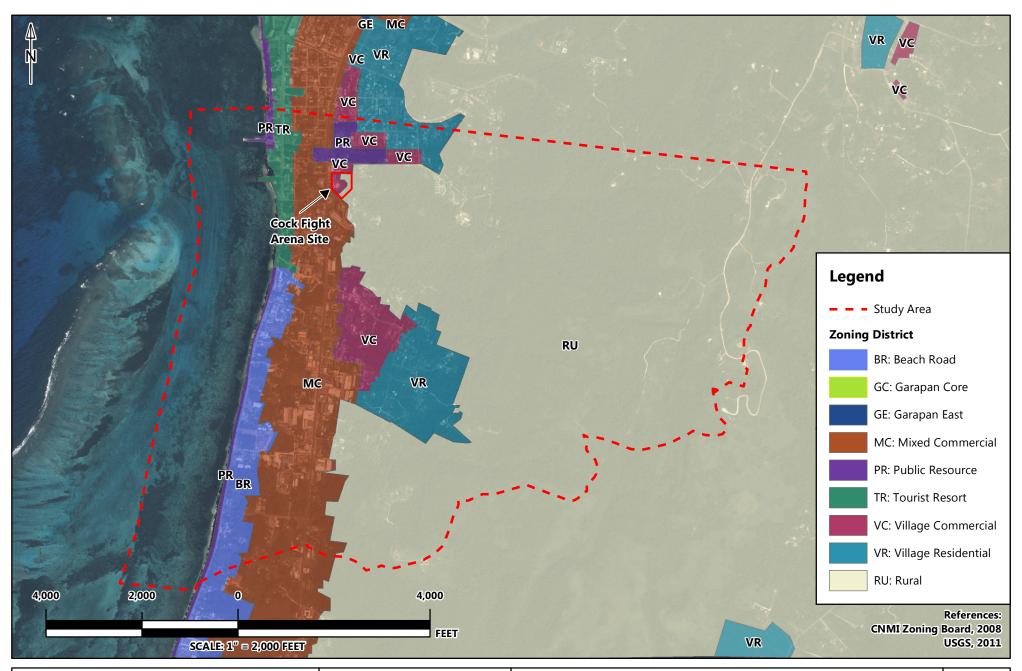

22 Under the No Action alternative no changes to current land uses would occur. Therefore,

there would be no impact to land use within the study area.

#### Preferred Alternative

The Preferred Alternative would have insignificant impacts on land use within the study area. The proposed detention basin would represent a change in land use from periodic recreational use to public lands used as a detention basin. Since the proposed detention basin site is only used periodically for recreational use as a Cock Fight Arena, and since the proposed action would benefit the public and the surrounding environment, there

would not be significant impacts to land use.

-ÇiEnvironet, Inc	•
-------------------	---

PROJECT NO.: 1057	ENVIRONMENTAL ASSESSMENT	
DATE: APRIL, 2013	SAIPAN LAGOON AQUATIC ECOSYSTEM RESTORATION STUDY	FIGURE
DRAWN BY: CB	LAND USE PLAN REFERENCE MAP	7
REVIEWED BY: MA	SAIPAN, CNMI	

## 1 3.10 VISUAL AESTHETICS

## 2 **3.10.1 Existing Conditions**

- 3 The study area is moderately urbanized, but retains the visitor quality of the urban center
- 4 of Garapan with a mixture of quaint stores surrounded by pristine scenic views of
- 5 mountains to the east, vast ocean to the west, and undeveloped coastal land stretching
- 6 north and south.

7

- 8 The study area is located in a coastal lowland strip that stretches north and south along
- 9 the west side of the island. The coast is fronted by a barrier reef on the west, and to the
- 10 east the island is characterized by a mountainous interior. The study area is composed of
- 11 clustered buildings and residences surrounded by lush vegetation. Scenic locations
- remain along the coast and in the less developed areas of the island.

## 13 **3.10.2 Potential Impacts and Mitigation**

- 14 No Action
- 15 Under the No Action alternative there would be no change to visual and aesthetic
- 16 resources within the study area. Therefore, there would be no impact to visual and
- 17 aesthetic resources.
- 18 Preferred Alternative
- 19 The Preferred Alternative would result in insignificant impacts to visual and aesthetic
- 20 resources within the study area during the construction period. The presence of
- 21 construction equipment and activity at the proposed detention basin site would be visible
- 22 to the surrounding environment. However, since the construction period would be
- 23 temporary, impacts would be insignificant. The proposed detention basin would be a
- low-lying structure, most of which would be a below-grade depression that would not
- create significant visual impacts.

## 26 3.11 RECREATION/RESOURCE USE

## 27 **3.11.1 Existing Conditions**

- 28 Recreational activities in Saipan consist of both terrestrial and water-based activities
- associated with the tourism industry, as well as local participation. The Garapan region is
- 30 located north of the study area, and is the largest resort/tourism center on the island. The
- 31 Saipan Lagoon provides a large, calm, and relatively shallow area of water that is used
- 32 for a variety of aquatic recreational activities including swimming, windsurfing, surfing,
- fishing, jet skiing, kayaking, snorkeling, scuba diving, and water skiing. Terrestrial
- 34 recreational activities for both tourists and residents include shopping, indoor shooting
- ranges, and a variety of restaurants, night clubs and bars. A recreational, paved beach
- 36 path stretches south from Garapan approximately two miles and provides a scenic,
- 37 protected area for walking, bike riding, and jogging.

- 1 Golfing, mountain biking and hiking are also popular recreational activities in Saipan.
- 2 There are also several shoreline grottos on the northern end of the island that are popular
- 3 scuba diving destinations for numerous tour companies on the island.

## 4 3.11.2 Potential Impacts and Mitigation

- 5 No Action
- 6 Under the No Action alternative there would be no impacts to recreation or resource use
- 7 since there would be no use of additional recreational areas or resources.
- 8 Preferred Alternative
- 9 Under the Preferred Alternative, the Cock Fight Arena would be impacted because it
- would no longer be used for recreational purposes. However, since the site is not used on
- 11 a regular basis, and could be relocated, impacts would be less than significant. The
- 12 Preferred Alternative would require the commitment of natural resources such as
- 13 aggregate for concrete and petroleum products to fuel construction equipment. The
- amount of resources needed to complete the detention basin would not represent a
- significant commitment of resources. Therefore, impacts to recreation and resource use
- would be insignificant.

20

#### 17 3.12 ECONOMIC AND SOCIAL RESOURCES

## 18 **3.12.1 Existing Conditions**

19 Table 7 shows selected social and economic information for the CNMI.

**Table 7: CNMI Social and Economic Characteristics** 

Population	53,833	
Median Age	33.4	
Ethnic Origin or Race (% of total population)		
Native Hawaiian and	34.9	
other Pacific Islander		
Asian	49.9	
Other Race	15.2	
Total Households	16,035	
Average Household	3.80	
Size		
Labor Force	27,968	
Unemployment Rate	8.1 %	
Industry or Trade(% of total workforce)		
Arts, Entertainment,	22.2	
Recreation, and		
Accommodation and

Educational Services,	12.4	
and Health Care and		
Social Assistance		
Retail Trade	10.7	
Other Services,	10.3	
except Public		

**Table 7: CNMI Social and Economic Characteristics** 

Administration	
Public Administration	9.7
Construction	7.2
Other Industry	27.5

- 1 Source: American Fact Finder, 2010.
- 2 As shown in Table 7, arts, recreation and accommodation and food services offer the
- 3 greatest number of jobs to residents, followed by education, health care and social
- 4 assistance. The unemployment rate in the CNMI is 8.1 %.

## 5 3.12.2 Potential Impacts and Mitigation

- 6 No Action
- 7 Under the No Action alternative there would be no impact to economic and social
- 8 resources. There would be no jobs created or lost, or any action resulting in an impact to
- 9 social systems or services.
- 10 Preferred Alternative
- 11 Under the Preferred Alternative there would be beneficial impacts to economic and social
- 12 resources from added construction employment, as well as ongoing employment
- associated with the operation and maintenance of the proposed detention basin.

# 3.13 CUMULATIVE IMPACTS ASSOCIATED WITH THE PREFERRED ALTERNATIVE

Cumulative impacts are two or more individual effects which, when considered together, compound or increase the overall impact. Cumulative impacts can arise from the individual effects of a single action or from the combined effects of past, present, or future actions. Thus, cumulative impacts can result from individually minor but collectively significant actions taken over a period of time. The cumulative impacts of the proposed action along with past and reasonably foreseeable future projects proposed were assessed based upon available information.

222324

25

26

27

28

29

30

31

14

15

16

17

18

19

20

21

CNMI Office of the Secretary of Public Works (DPW) plans to improve Route 33 (Beach Road) by repairing or reconstructing the existing pavement structure, improving surface drainage conditions, and incorporating pedestrian and bike lane features where warranted. Drainage improvements are proposed for the roadway improvement project and are not expected to result in any adverse cumulative impacts when implemented in conjunction with the Preferred Alternative. BMPs implemented in conjunction with construction activities under the Preferred Alternative are not expected to result in cumulative adverse impacts. No other projects are known to be planned in the surrounding area that would compound or increase the impact of the Preferred Alternative.

32 33 34

35

The Preferred Alternative would not lead to any adverse cumulative impacts. The proposed detention basin under the Preferred Alternative would lead to beneficial

 cumulative impacts to water quality in surface water and the Saipan Lagoon. The detention basin would remove sediment and other suspended solids from stormwater runoff within the study area. This would lead to a reduction in sediment loads and other pollutants entering the lagoon, which would improve water quality within the affected area of the lagoon. An improvement in water quality could lead to ecosystem restoration for lagoon habitats.

## 4. RELATIONSHIP TO ENVIRONMENTAL REGULATIONS

#### 4.1 FEDERAL CLEAN WATER ACT

- 3 The Clean Water Act (CWA) establishes the basic structure for regulating discharges of
- 4 pollutants into the waters of the U.S. and regulating quality standards for surface waters.
- 5 The federal CWA prohibits the discharge of dredged or fill material into waters of the
- 6 U.S. without authorization from the USACE. Because construction BMPs would be
- 7 implemented under the Preferred Alternative, construction related runoff of any soil or
- 8 fill material would be controlled. There would be no discharge of dredged or fill material,
- 9 and a CWA authorization under Section 404 would not be required.

## 10 4.2 FEDERAL CLEAN AIR ACT (CAA)

- 11 The federal CAA (42 USC 7401) requires the adoption of national ambient air quality
- standards to protect public health, safety, and welfare from known or anticipated effects
- of air pollution. The CNMI utilizes the NAAQS regulated by the EPA to provide
- established sets of ambient air quality standards to protect human health and welfare.
- 15 Administrative Code DEQ Chapter 65-10: Air Pollution Regulations establishes
- standards to insure that air resources are protected against pollution and do not constitute
- a health hazard. Since impacts to air quality from the Preferred Alternative would only
- 18 include exhaust emissions from construction equipment and vehicles during the
- 19 construction of the proposed detention basins, there would be less than significant
- 20 impacts to air quality.

1

2

## 21 4.3 EXECUTIVE ORDER (EO) – PROTECTION OF CORAL REEFS

- 22 EO 13089 states that "all Federal agencies whose actions may affect U.S. coral reef
- ecosystems shall: (a) identify their actions that may affect U.S. coral reef ecosystems; (b)
- 24 use their programs and authorities to protect and enhance the conditions of such
- ecosystems; and (c) to the extent permitted by law, ensure that any actions they authorize,
- 26 fund or carry out will not degrade the conditions of such ecosystems." Potential adverse
- 27 impacts from construction runoff under the Preferred Alternative would be mitigated by
- 28 the institution of BMPs, including silt fences and other engineering controls. The
- 29 proposed detention basin would remove sediments and other suspended solids from
- 30 runoff waters before entering the lagoon. This would contribute to improved coral
- 31 health. Therefore, there would be beneficial impacts to coral reefs within the study area
- 32 under the Preferred Alternative.

33

#### 4.4 COASTAL ZONE MANAGEMENT ACT (CZMA)

- 34 The CZMA of 1972, as amended (16 USC 1451 et seq.), is administered in Saipan by the
- 35 CNMI CRMO. The CZMA affects all projects on federal lands and/or involving federal
- 36 agencies and requires federal agencies to conduct their planning, management,
- development and regulatory activities in a manner consistent with the state's coastal zone
- 38 management (CZM) program. The CZM program objectives and policies are to provide
- 39 coastal recreational opportunities; preserve and protect historic, scenic and coastal
- 40 ecosystem resources; provide economic uses; reduce coastal hazards; improve public

- 1 awareness in coastal zone management; and manage development within the coastal
- 2 zone. The entire island of Saipan is located within the coastal zone. The CNMI CRMO
- 3 is the lead sponsor for the proposed project, the purpose of which is to reduce the amount
- 4 of sediment and other suspended solids from entering the lagoon via stormwater runoff.
- 5 Therefore, the Preferred Alternative would comply with the CRMO Regulation 15-10;
- 6 Coastal Resources Rules and Regulations, and would have a beneficial impact on coastal
- 7 resources.

## 8 4.5 THE ENDANGERED SPECIES ACT (ESA)

- 9 The ESA of 1973, Section 7 requires federal agencies to conduct consultation to
- determine effects of an action on threatened and endangered species or their designated
- 11 habitats.
- 12 The USFWS and the CNMI DLNR DFW have jurisdiction over endangered and
- threatened terrestrial flora, fauna, and birds. NOAA, through the National Marine
- 14 Fisheries Service has jurisdiction over marine mammals and fish.
- 15 The CNMI DLNR DFW provided a list of species of concern that exist within the CNMI.
- Once the specific areas for development are delineated during the permit process, the
- 17 CNMI DLNR DFW will complete a biological survey of the proposed development sites
- and determine the need for any mitigation measures if any species of concern are found
- 19 to exist within the development areas. With these mitigation measures in place there
- would be no impacts to biological resources under the Preferred Alternative.

### 21 4.6 FISH AND WILDLIFE COORDINATION ACT

- 22 The U.S. Fish and Wildlife Coordination Act and its amendments require Federal
- 23 agencies to consult with and give equal consideration to other water resources
- 24 development programs regarding the fish and wildlife impacts of projects that propose to
- 25 impound, divert, channel, or otherwise alter a body of water.
- 26 The USFWS has conducted various biological surveys in Saipan, including the Final
- 27 Coordination Act Report for the Garapan Flood Control Study and the Biological
- 28 Opinion Study for Chalan Laulau. These reports are included in Appendix C. An
- 29 inshore lagoon area seagrass and associated fauna survey was conducted in the study area
- 30 in May of 2002 by the MMT, and a study of seagrass and macroalgal assemblages in
- 31 Saipan Lagoon was also conducted in 2010 (Houk, and R. Camacho, 2010). A wetlands
- 32 conservation plan for the CNMI was completed by the CNMI Department of Lands
- Natural Resources (DLNR) in 1989 (DLNR, 1989). A wetland site assessment conducted
- 34 by CRMO personnel in November of 2003 found no evidence of wetlands within the
- 35 affected portions of the study area.
- 36 Subsection 2(h) of FWCA-Exempt Project Activities. FWCA exempts surface water
- impoundments less than 10 acres. "The provisions of the Act shall not be applicable to
- projects for the impoundment of water where the maximum surface area is less than 10
- 39 acres." The proposed action does not include work in streams nor any body of waters;
- 40 channelization; diversion of streams and storm drains etc. All work shall be done on
- 41 urban land determined to be absent of fish and wildlife.

- 1 Water-diversion structures in the form of a retention basin are included in the proposed
- 2 construction activities for this EA. However, the construction of the retention basin
- 3 would ultimately reduce the discharge of pollutants into the lagoon ecosystem. As a
- 4 result, the Preferred Alternative would have an indirect beneficial impact on the fish and
- 5 wildlife that exist within the lagoon ecosystem.

## 6 4.7 MARINE MAMMAL PROTECTION ACT (MMPA)

- 7 The Marine Mammal Protection Act (MMPA) was enacted in 1972 in order to prohibit
- 8 the "take" of marine mammals within U.S. waters, the "take" of marine mammals by
- 9 U.S. citizens on the high seas, and the importation of marine mammals and marine
- mammal products into the U.S. No marine mammals will be "taken" incidental to the
- 11 implementation of the Preferred Alternative. In addition, marine mammals are not
- 12 known to frequent the lagoon ecosystem. If marine mammals did inhabit the lagoon
- ecosystem they would benefit from the restorative impacts that the retention basins would
- provide. As a result, the proposed construction activities in this EA should not be a
- 15 concern regarding the MMPA.

# 16 4.8 MAGNUSON-STEVENS FISHERY CONSERVATION AND 17 MANAGEMENT ACT

- 18 The Magnuson-Stevens Fishery Conservation and Management Act was created in 1976
- and amended twice in 1996 and 2006. The Act was enacted to serve the following seven
- 20 purposes:

22

26

27

28

29

30

31

35

- acting to conserve fishery resources;
  - supporting enforcement of international fishing agreements;
- promoting fishing in line with conservation principles;
- providing for the implementation of fishery management plans which achieve optimal yield;
  - establishing Regional Fishery Management Councils to steward fishery resources through the preparation, monitoring, and revising of plans which enables stakeholders to participate in the administration of fisheries and consider social and economic needs:
  - developing underutilized fisheries; and
    - protecting essential fish habitats.
- 32 The detention basin proposed in this EA will serve to improve the lagoon ecosystem. As
- a result, the Preferred Alternative would have a beneficial impact on the local fishery
- 34 centered in the study area.

## 4.9 COASTAL RESOURCE MANAGEMENT ACT

- 36 This act requires that parties proposing anthropogenic activities affecting or which may
- 37 affect the coastal resources of the CNMI apply for a CRMO Permit. A wetland site
- 38 assessment conducted by CRMO personnel in November of 2003 found no evidence of
- 39 wetlands in the proposed detention basin site. No other Areas of Particular Concern
- 40 (APCs) were identified within the boundaries of the study area.

## 4.10 EXECUTIVE ORDER (EO) 13089 ON COASTAL REEF PROTECTION

- 2 EO 13089 directs all Federal agencies to protect and manage U.S. coral reef ecosystems
- 3 by identifying actions that may affect these ecosystems, and to protect and enhance them
- 4 to the extent permissible by law. As the objective of the project is to restore the
- 5 ecosystem of the lagoon, the Preferred Alternative would not adversely impact the
- 6 existing coral reef ecosystem and may enhance its condition over time.

## 7 4.11 SECTION 106 NATIONAL HISTORIC PRESERVATION ACT

- 8 Section 106 of the NHPA seeks to accommodate historic preservation concerns with the 9 needs of Federal endeavors through consultation among the agency official, CNMI
- Historic Preservation Officer, and other parties with an interest in the effects of the
- project on cultural, archaeological and historic resources and properties. The purpose of
- 12 consultation is to identify cultural, archaeological and historic resources and properties
- potentially affected by the project, assess its effects and seek ways to avoid, minimize or
- mitigate any adverse effects on known resources.

15 16

17

18

Pursuant to Section 106 of the NHPA of 1966 (as amended) and its implementing regulations (36 CFR 800), project alternatives which might affect properties listed or eligible for listing on the National Register of Historic Places are subject to the provisions of this Act.

USACE and CNMI Archeological staff had meetings and field visits pertaining to the study area as well as a formal archaeological investigation in August, 2003. Preferred Alternative would have no adverse effect to historic properties. However, prior to the start of any ground breaking construction activities associated with this project, an AMP shall be completed by a qualified archaeologist and submitted to the CNMI HPO for review and comments before its finalization prior to groundbreaking activities. Further, monitoring by a qualified archeologist is recommended for any earthmoving activities to ensure proper treatment of any possible subsurface historical, cultural and/or archeological resources encountered. A full archaeological report documenting the results of the archaeological monitoring activities shall also be submitted at the end of all construction activities to the CNMI HPO for the agency's library and files. Based on USACE POH Archaeological evaluation of the project area, it is concluded that the presence of a qualified archaeologist during construction will ensure the protection of potentially significant cultural resources including human burial remains that may be present subsurface within the project's area of potential effect. USACE POH has concluded that with the presence of a qualified archaeologist monitor during all new ground breaking construction activities as well as the submittal of a final AMP and postmonitoring archaeological report to CNMI HPO, a determination can be made that the Preferred Alternative shall have no adverse effect to historic properties.

September 2013

## 4.12 EO 12898 – ENVIRONMENTAL JUSTICE IN MINORITY POPULATIONS AND LOW-INCOME POPULATIONS AND EO 13045 – PROTECTION OF CHILDREN FROM ENVIRONMENTAL HEALTH AND SAFETY RISKS

- 4 EO 12898 states that "each Federal agency shall make achieving environmental justice 5 part of its mission by identifying and addressing, as appropriate, disproportionately high
- 6 and adverse human health or environmental impacts of its programs, policies, and
- 7 activities on minority populations and low-income populations in the United States and
- 8 its territories and possessions, the District of Columbia, the Commonwealth of Puerto
- 9 Rico, and the CNMI."

1

2 3

- 10 No significant adverse environmental impacts are anticipated as a result of the Preferred
- 11 Alternative. The Preferred Alternative involves a public infrastructure project to reduce
- the amount of sediment and other harmful constituents from reaching the Saipan lagoon.
- 13 There would be no significant adverse impacts to minority and low-income populations
- 14 in Saipan. No disproportionate adverse effects on children are expected to result from
- implementation of the Preferred Alternative. The Preferred Alternative would result in
- beneficial impacts to public health and safety, and the environment.

# Section 1 Hydrology

Three low-lying areas in the West Takapochao watershed were selected for evaluation as possible drainage detention basins. These sites include vacant land adjacent to Quartermaster Road, the China House, and the Cockfight Arena; see Figure 1. These three areas currently flood during heavy rains.

During heavy rains the initial rainfall will produce the most sediment, nutrients and pollutants, known as the "first flush." In order to represent this "first flush" a one-hour intensity storm over a one hour duration has been applied to the analyses. Three storm events were evaluated in this report; 2-year, 5-year, and 10-year recurrence storms. Storm event data were utilized from the "Rainfall – Frequency Study, Saipan Commonwealth of Northern Marianas Islands, Contract No. DACA83-01-D-0014", prepared by Environet, Incorporated, dated April 2003.

Table 1: Saipan International Airport Rainfall Data – 60 minute Duration Storm Events

Return Frequency	Cumulative Rainfall (inches)	Rainfall Intensity (inches/ hour) <sup>1</sup>
V	3.06	3.06
$f X_{10}$	3.00	3.00
Λ <sub>5</sub>	1.02	2.01
$X_2$	1.93	1.93

1 From Table 4-6 and Table 4-7 in the "Rainfall – Frequency Study"

The watershed analysis for each storm and site was performed using the computer software program Hydrologic Modeling System HEC-HMS, version 3.5 and can be found in Appendix A. The Soil Conservation Service (now the Natural Resource Conservation Service) curve number was applied to the analyses along with the SCS unit hydrograph to symbolize the direct runoff over the watersheds. The lag time for the unit hydrograph was assumed to equal the time of concentration. No baseflow is assumed in the analyses. The simulations were ran over a 24-hour time period.

# Section 2 Hydraulics

HEC-HMS version 3.5 was also used to perform the analysis on the proposed detention basins. Elevation-area functions were used to specify the storage relationships. The outlet structure routing method was used to perform the reservoir routing. The simulations were routed through reinforced concrete outlet pipes (RCP) that were sized according to the analysis and existing site conditions. The RCP outlet pipes are to be wrapped in filter cloth and gravel, and are to be located 1'-2' above the bottom of the detention basin. This will allow sediment to settle out in the basin and will require periodic removal of sediment from the basins. The simulations were ran over a 24-hour time period.

Each watershed was analyzed separately for the three storm events. A preliminary design of the required improvements was completed for each event and each site. The preliminary designs are further explained in detail in the following sections. Each design is based upon 100% of the design storm runoff passing through the detention basin. The analysis assumes that the topographic conditions and existing drainage facilities adequately convey storm flows to the proposed detention basins. Detailed as-built information and condition surveys about existing storm drain systems were not available; nor were detailed surveys of the proposed sites. This information will be necessary for implementation of the final design of the proposed detention basins. For the purposes of preliminary design and comparison, assumptions were made regarding the sites and existing drain systems. These assumptions are identified in the following sections and/or on the figures. It should also be noted that the Quartermaster Site and the Cock Fight Arena are currently on private property. This report does not address acquiring such properties and that it is assumed that all lands used for the proposed detention basins can or will be acquired by the CNMI Government.

# Section 3 Quartermaster Site

## 3.1 Existing Conditions

The Quartermaster Site is located at the northwest corner of the intersection of Quartermaster Road and Middle Road. The site is currently vacant and overgrown with vegetation. The site generally slopes to the southwest corner at approximately 4-5%.

The watershed which is tributary to the site is approximately 109 acres. The wtershed is mostly undeveloped, mountainous terrain. The bottom of the watershed, adjacent to Middle Road is more moderately sloped and developed with residential and commercial buildings, roads, and associated improvements. The watershed has an average slope of approximately 23%.

The storm runoff concentrates along the east side of Middle Road at a low point on the northern side of the Quartermaster Road intersection. There is an existing catch basin at this location which will continue to be utilized.

Condition of existing drainage facilities is unknown and may require repair or replacement. Existing facilities were assumed as shown on figures 2.1, 2.2 and 2.3.

## 3.2 2-Year Storm Event

The 2-year storm event will produce a peak runoff of approximately 20.8 cfs. The runoff will be routed through a proposed detention basin providing approximately 1.52 ac-ft of storage from elevations 23 feet - 32 feet. Discharge from the detention basin will enter an existing swale via an 18 inch RCP outlet and flow along the north side of Quartermaster Road running westward toward Beach Road and the Lagoon. Figure 2.1 depicts the required improvements to the Quartermaster site to detain the 2-year storm event. With the proposed improvements, the detention basin will pond approximately to elevation 26.8 feet, and the peak discharge from the detention basin will be approximately 7.7 cfs.

## 3.3 5-Year Storm Event

The 5-year storm event will produce a peak runoff of approximately 75.0 cfs. The runoff will be routed through a proposed detention basin providing approximately 4.89 ac-ft of storage from elevations 23 feet – 32 feet. Discharge from the detention basin will enter an existing swale via an 18 inch RCP outlet and flow along the north side of Quartermaster Road running westward toward Beach Road and the Lagoon. Figure 2.2 depicts the required improvements to the Quartermaster site to detain the 5-year storm event. With the proposed improvements, the detention basin will pond approximately to elevation 27.9 feet, and the peak discharge from the detention basin will be approximately 12.4 cfs.

## 3.4 10-Year Storm Event

The 10-year storm event will produce a peak runoff of approximately 118.5 cfs. The runoff will be routed through a proposed detention basin providing approximately 6.92 ac-ft of storage from elevations 23 feet – 32 feet. Discharge from the detention basin will enter an existing swale via an 18 inch RCP outlet and flow along the north side of Quartermaster Road running westward toward Beach Road and the Lagoon. Figure 2.3 depicts the required improvements to the Quartermaster site to detain the 10-year storm event. With the proposed improvements, the detention basin will pond approximately to elevation 28.9 feet, and the peak discharge from the detention basin will be approximately 14.5 cfs.

## Section 4 China House Site

## 4.1 Existing Conditions

The China House Site is located near the China House Restaurant and the driving range, about halfway between Middle Road and Beach Road. The site is currently undeveloped and overgrown with vegetation. However there are abandoned structures on the property which will need to be demolished. The site generally slopes to the west at approximately 3.5%.

The watershed which is tributary to the site is approximately 344 acres. The watershed is mixed between undeveloped, mountainous terrain and areas developed with residential and commercial buildings, roads, and associated improvements. The watershed has an average slope of approximately 16%.

The storm runoff concentrates along the east side of Middle Road at a low point in the road. There is an existing catch basin at this location which will continue to be utilized. Each storm event requires improvements starting at this existing catch basin, which are further detailed in the following sections.

Condition of existing drainage facilities is unknown and may require repair or replacement. Existing facilities were assumed as shown on figures 3.1, 3.2 and 3.3.

## 4.2 2-Year Storm Event

The 2-year storm event will produce a peak runoff of approximately 51.9 cfs. The runoff will be routed through a proposed detention basin providing approximately 4.77 ac-ft of storage from elevations 20 feet – 29 feet. An 18 inch RCP outlet will discharge from the detention basin to an existing double 30 inch culvert under Beach Road, discharging to the Lagoon. Figure 3.1 depicts the required improvements to the China House site to detain the 2-year storm event. With the proposed improvements, the detention basin will pond approximately to elevation 24.4 feet, and the peak discharge from the detention basin will be approximately 15.0 cfs.

## 4.3 5-Year Storm Event

The 5-year storm event will produce a peak runoff of approximately 178.6 cfs. The runoff will be routed through a proposed detention basin providing approximately 13.54 ac-ft of storage from elevations 19 feet – 29 feet. An 18 inch outlet pipe will discharge from the detention basin to an existing double 30 inch culvert under Beach Road, discharging to the Lagoon. Figure 3.2 depicts the required improvements to the China House site to detain the 5-year storm event. With the proposed improvements, the detention basin will pond approximately to elevation 26.8 feet, and the peak discharge from the detention basin will be approximately 15.6 cfs.

## 4.4 10-Year Storm Event

The 10-year storm event will produce a peak runoff of approximately 284.0 cfs. The runoff will be routed through a proposed detention basin providing approximately 15.84 ac-ft of storage from elevations 18 feet – 30 feet. A 36 inch outlet pipe will discharge from the detention basin to an existing double 30 inch culvert under Beach Road, then discharging to the Lagoon. Figure 3.3 depicts the required improvements to the China House site to detain the 10-year storm event. With the proposed improvements, the detention basin will pond approximately to elevation 27.9 feet, and the peak discharge from the detention basin will be approximately 91.1 cfs.

# Section 5 Cock Fight Arena Site

## 5.1 Existing Conditions

The Cock Fight Arena Site is located on the east side of Middle Road, surrounding the existing Cock Fight Arena. The site is currently developed as a Cock Fight Arena, and portions were utilized as a quarry. The site generally slopes to the quarry pit.

The watershed which is tributary to the site is approximately 413 acres. The watershed is mainly undeveloped, mountainous terrain with some minor areas developed with residential and commercial buildings, roads, and associated improvements. The watershed has an average slope of approximately 12%.

Condition of existing drainage facilities is unknown and may require repair or replacement. Existing facilities were assumed as shown on figures 4.1, 4.2 and 4.3.

## 5.2 2-Year Storm Event.

The 2-year storm event will produce a peak runoff of approximately 20.9 cfs. The runoff will be routed through a proposed detention basin providing approximately 11.85 ac-ft of storage from elevations 37 feet – 45 feet. An 18 inch outlet pipe will discharge from the detention basin to the Lagoon following existing paved roadways. Figure 4.1 depicts the required improvements to the Cock Fight Arena site to retain the 2-year storm event. The pit is currently sufficiently sized to accommodate the 2-year storm event; however, inlet improvements are required and outlet improvements are recommended. With the proposed improvements, the detention basin will pond approximately to elevation 40.3 feet, and the peak discharge from the detention basin will be approximately 4.4 cfs.

Based upon the minimal topographic information provided, it appears that the Cock Fight Arena's finish floor is approximately 43 feet in elevation. Additional investigation of the Arena and the pit should be performed to verify that ponding will not flood the Arena.

## 5.3 5-Year Storm Event

The 5-year storm event will produce a peak runoff of approximately 95.9 cfs. The runoff will be routed through a proposed detention basin providing approximately 11.85 ac-ft of storage from elevations 37 feet – 45 feet. An 18 inch outlet pipe will discharge from the detention basin to the Lagoon following existing paved roadways. Figure 4.2 depicts the required improvements to the Cock Fight Arena site to detain the 5-year storm event. The pit is currently sufficiently sized to accommodate the 5-year storm event; however, inlet and outlet improvements are required. With the proposed improvements, the detention basin will pond approximately to elevation 43.4 feet, and the peak discharge from the detention basin will be approximately 14.0 cfs.

Based upon the minimal topographic information provided, it appears that the Cock Fight Arena's finish floor is approximately 43 feet in elevation. Additional investigation of the Arena and the pit should be performed to verify that ponding will not flood the Arena. If flooding will occur, modifications can be made to the pit, or outlet structures. Alternatively, the Arena may be demolished.

## 5.4 10-Year Storm Event.

The 10-year storm event will produce a peak runoff of approximately 164.7 cfs. The runoff will be routed through a proposed detention basin providing approximately 14.23 ac-ft of storage from elevations 37 feet – 45 feet. A 24 inch outlet pipe will discharge from the detention basin to the Lagoon following existing paved roadways. Figure 4.3 depicts the required improvements to the Cock Fight Arena site to detain the 10-year storm event. Improvements to the pit will include some grading at the base of the existing pit, the walls of the pit and limits of the pit will not require expansion. In addition, inlet and outlet improvements are required. With the proposed improvements, the detention basin will pond approximately to elevation 44.6 feet, and the peak discharge from the detention basin will be approximately 30.3 cfs.

Based upon the minimal topographic information provided, it appears that the Cock Fight Arena's finish floor is approximately 43 feet in elevation. Additional investigation of the Arena and the pit should be performed to verify whether ponding will flood the Arena. It appears likely that the Arena will need to be demolished, or additional modifications will need to be made to the pit, or outlet structures.

## Section 6 Conclusion

For each of the alternatives the detention basins were designed to provide adequate storage, detention times and outlet design to reduce outflow and improve water quality.

In addition to the detention basins, each site will include a perimeter fence and a paved access driveway to the bottom of each basin for safety and maintenance.

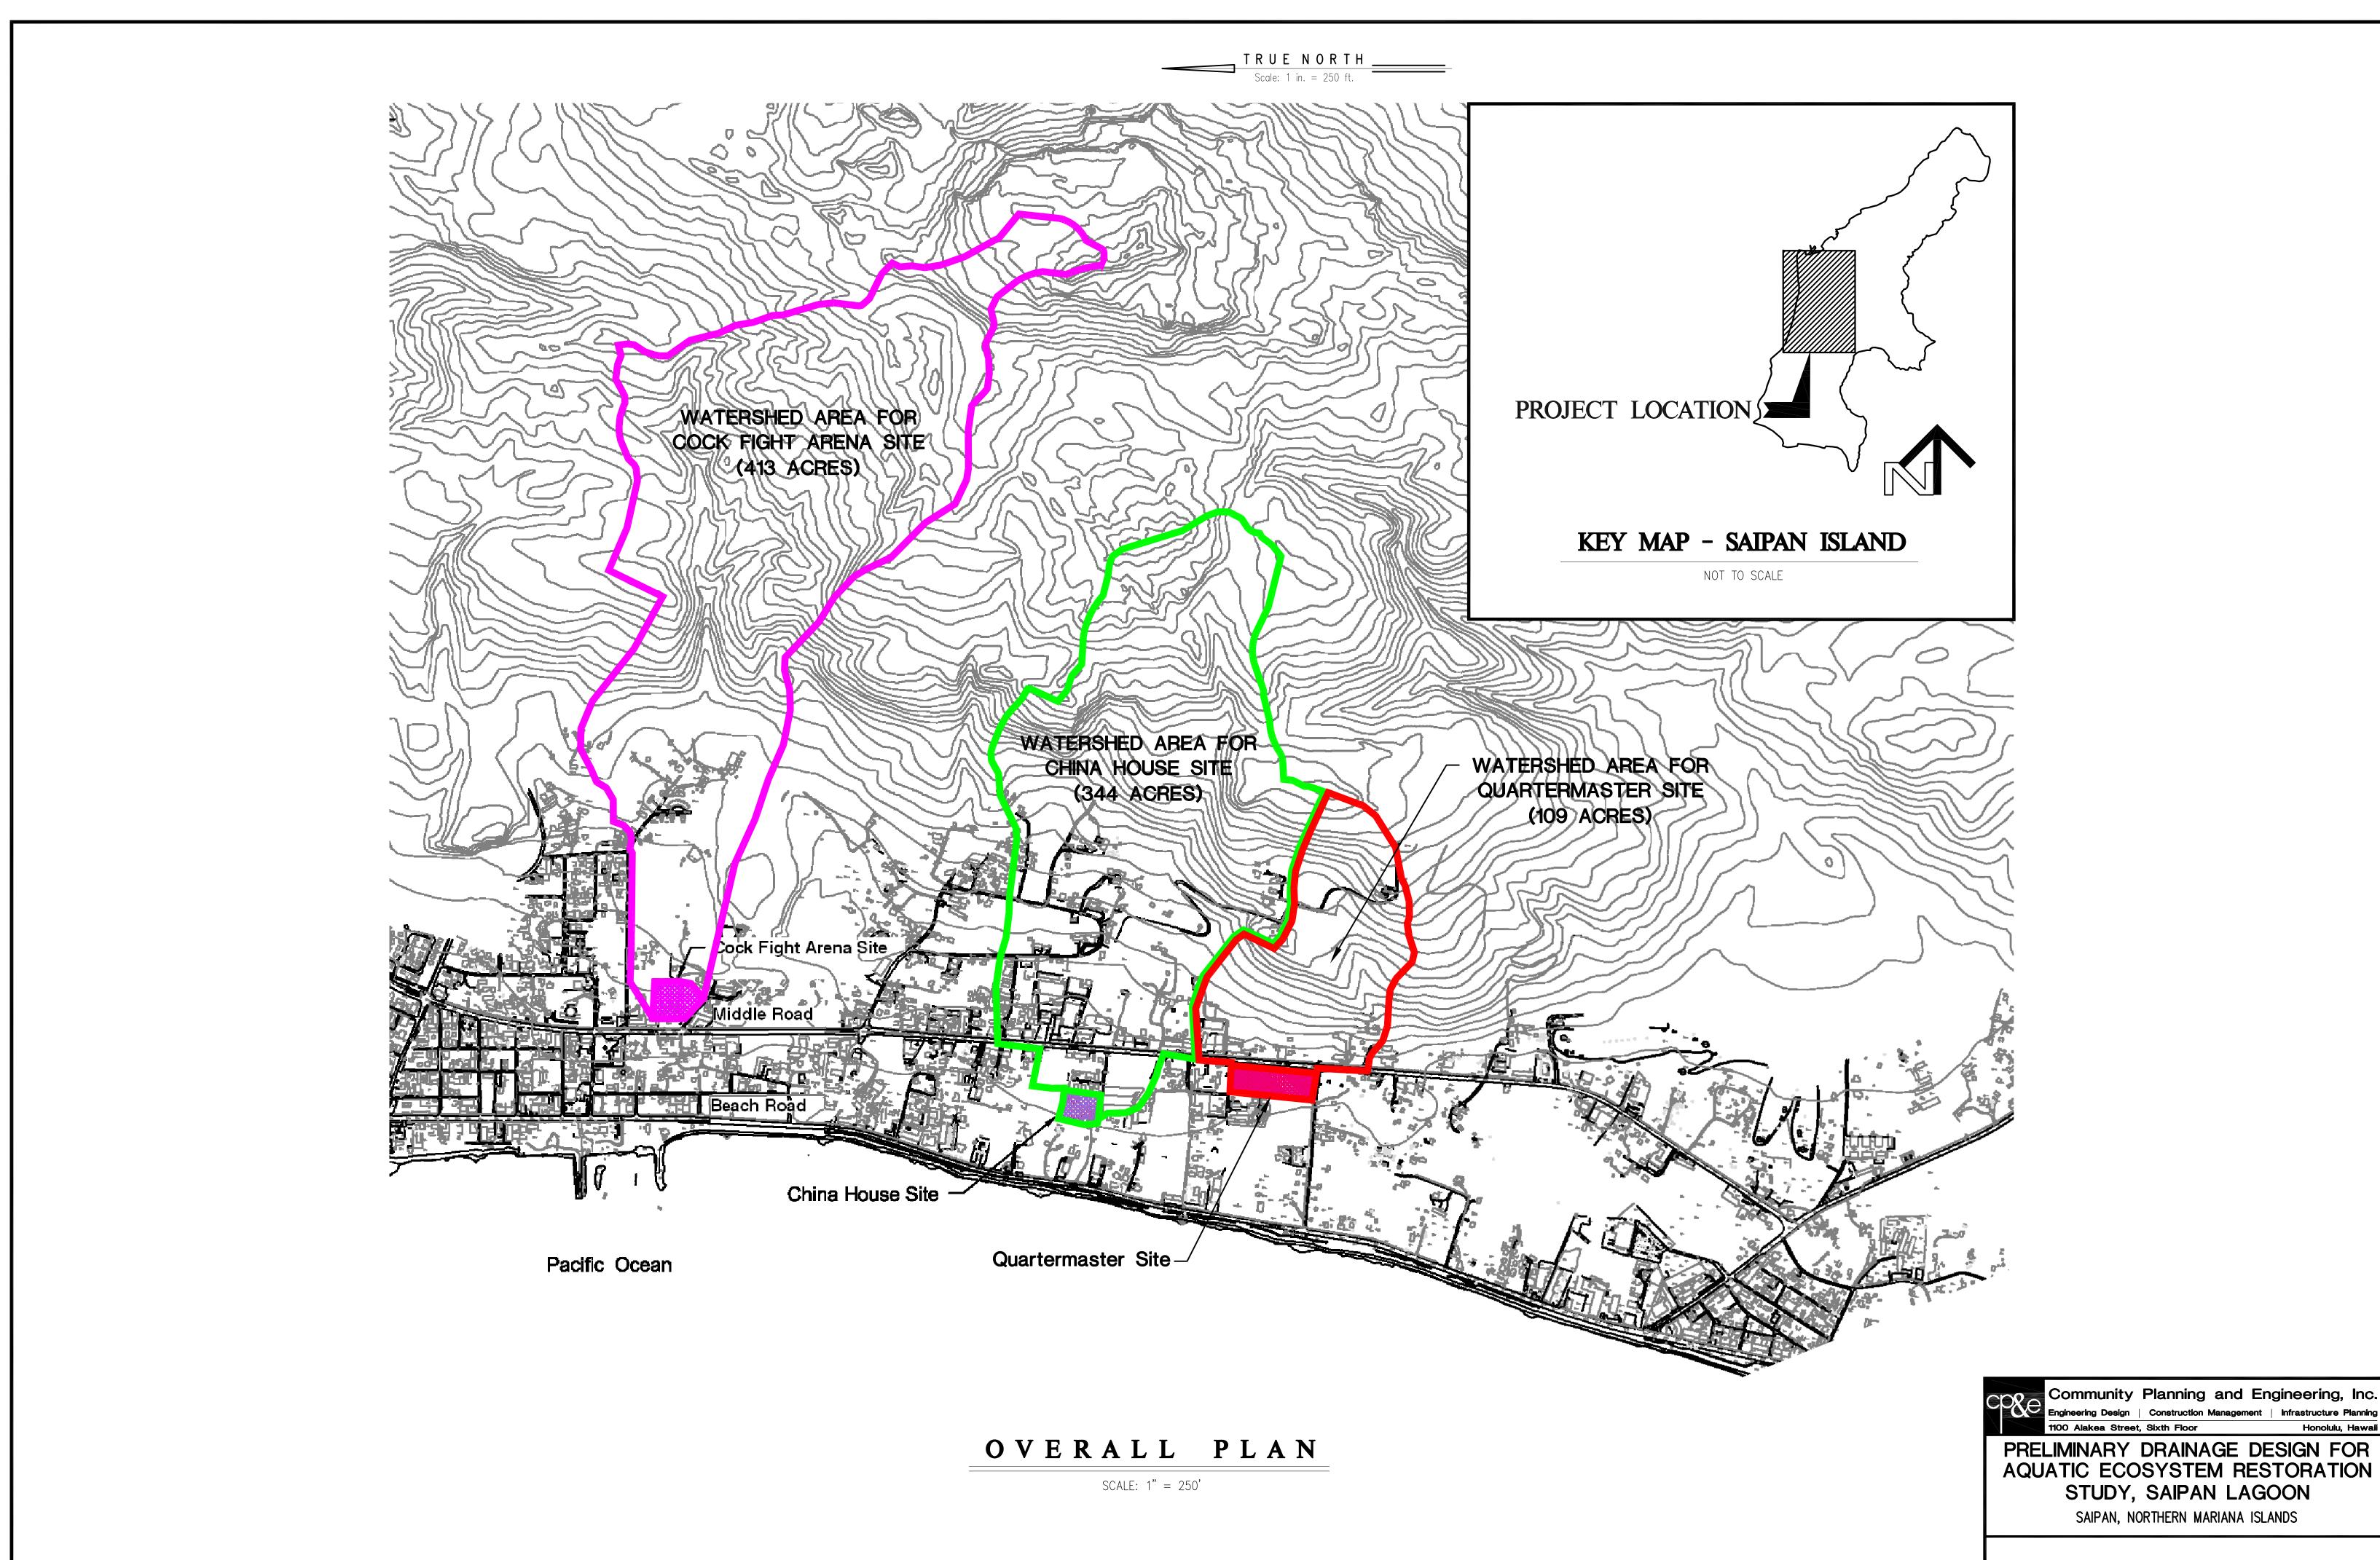

Additional topographic information will be required to finalize actual designs for any selected sites. Condition assessments of existing drainage facilities should also be performed.

The analysis provided herein along with the preliminary designs proposed, provide the U.S. Army Corps of Engineers (USACOE) with information to prepare cost-benefit analysis of the proposed sites and each of the storm event situations.

# Appendix A

## 1. Quartermaster Site: 2-Year Storm Event

## **Project: Saipon Lagoon Restoration**

Basin Model: Quarter Master 2-yr Storm Dec 27 14:11:52 HST 2011

## A. Quartermaster Drainage Basin:

#### A.1 Basin Model:

Area: 109 ac (0.1703 mi<sup>2</sup>)

CN: 65

Tc: 10.7 min Rainfall 2-year/1 hour: 1.93 in

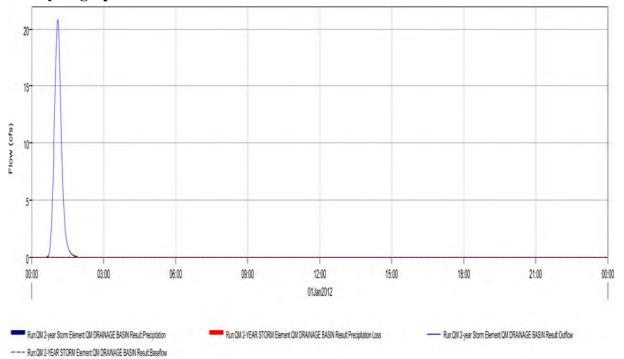

Loss Method: SCS Curve Number Transform Method: SCS Unit Hydrograph

#### **A.2 HEC-HMS Simulation Results:**

Simulation Run: QM 2-year Storm
Subbasin: QM Drainage Basin
Meteorologic Model: 2-year / 1 hour Storm
Control Specification: Control -24-hour

Computed Results			
Peak Discharge:	<b>20.8</b> (cfs)	Time of Peak Discharge:	01:06
Total Precipitation:	15.4 (ac-ft)	<b>Total Direct Runoff:</b>	0.6 (ac-ft)
Total Loss:	14.8 (ac-ft)	Total Baseflow:	0.0 (ac-ft)
<b>Total Excess:</b>	0.6 (ac-ft)	Discharge:	0.6 (ac-ft)

#### A3. Hydrograph

## **B. Quartermaster 2-Year Detention Basin:**

#### **B.1 Detention Basin Design:**

Elevation (ft)	Surf. Area (ac)	Increment Storage (ac-ft)	Cumulative Storage (ac-ft)
23.00	0.050	0.000	0.000
24.00	0.090	0.070	0.070
25.00	0.110	0.100	0.170
26.00	0.130	0.120	0.290
28.00	0.180	0.310	0.600
30.00	0.230	0.410	1.010
32.00	0.280	0.510	1.520

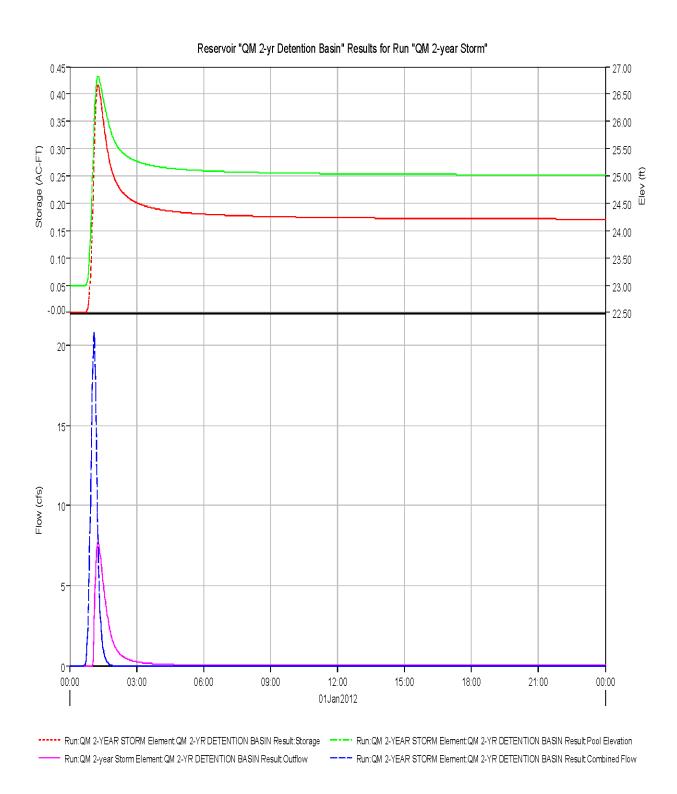

#### **B.2 Outlet Design:**

Pipe:	RCP culvert (end-section conforming to fill)
Diameter:	18 in
Length:	100 ft
Inlet Elevation:	25.00 ft
Outlet Elevation:	24.00 ft
Entrance Coefficient:	0.500
Slope:	0.010
Outlet Coefficient:	0.900
Mannings n:	0.013

#### **B.3 HEC-HMS Simulation:**

Simulation Run: QM 2-year Storm
Subbasin: QM Drainage Basin
Meteorologic Model: 2-year / 1 hour Storm
Control Specification: Control -24-hour

Computed Results			
Peak Inflow:	20.8 (cfs)	Time of Peak Inflow:	01:06
Peak Outflow:	7.7 (cfs)	Time of Peak Outflow:	01:16
<b>Total Inflow:</b>	0.6 (ac-ft)	Peak Storage:	0.4 (ac-ft)
<b>Total Outflow:</b>	0.4 (ac-ft)	Peak Elevation:	26.8 (ft)

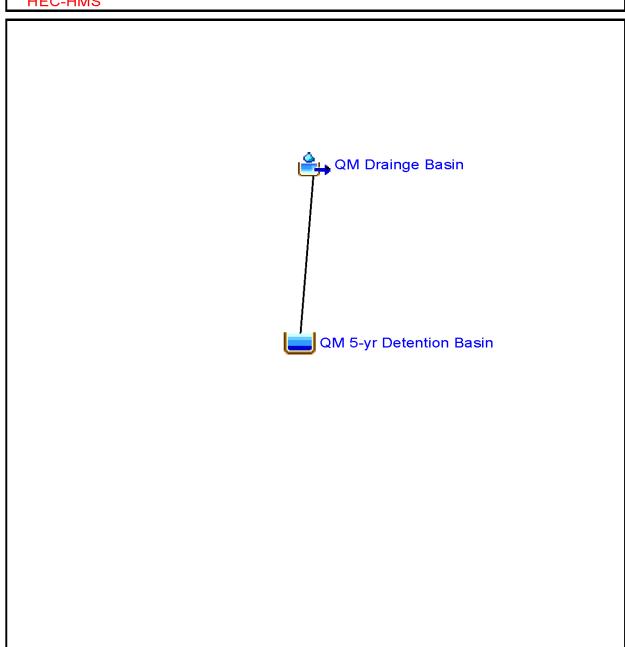

## 2. Quartermaster Site: 5-Year Storm Event

#### **Project: Saipon Lagoon Restoration**

Basin Model: Quarter Master 5-yr Storm Jan 12 07:57:36 HST 2012

## C.Quartermaster Drainage Basin:

#### A.1 Basin Model:

Area: 109 ac (0.1703 mi<sup>2</sup>)

CN: 65

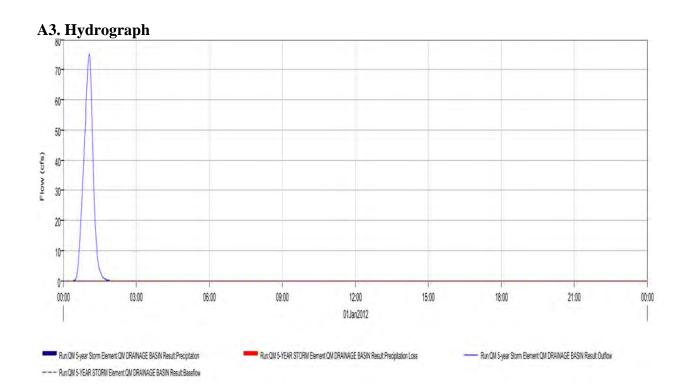

Tc: 10.7 min Rainfall 5-year/1 hour: 2.61 in

Loss Method: SCS Curve Number Transform Method: SCS Unit Hydrograph

#### **A.2 HEC-HMS Simulation Results:**

Simulation Run: QM 5-year Storm
Subbasin: QM Drainage Basin
Meteorologic Model: 5-year / 1 hour Storm
Control Specification: Control -24-hour

Computed Results			
Peak Discharge:	75.0 (cfs)	Time of Peak Discharge:	01:04
<b>Total Precipitation:</b>	22.7 (ac-ft)	<b>Total Direct Runoff:</b>	2.7 (ac-ft)
Total Loss:	20.0 (ac-ft)	<b>Total Baseflow:</b>	0.0 (ac-ft)
<b>Total Excess:</b>	2.7 (ac-ft)	Discharge:	2.7 (ac-ft)

## **D.Quartermaster 5-Year Detention Basin:**

#### **B.1 Detention Basin Design:**

Elevation (ft)	Surf. Area (ac)	Increment Storage (ac-ft)	Cumulative Storage (ac-ft)
23.00	0.180	0.000	0.000
24.00	0.460	0.320	0.320
25.00	0.480	0.470	0.790
26.00	0.510	0.495	1.285
28.00	0.570	1.080	2.365
30.00	0.630	1.200	3.565
32.00	0.690	1.320	4.885

#### **B.2 Outlet Design:**

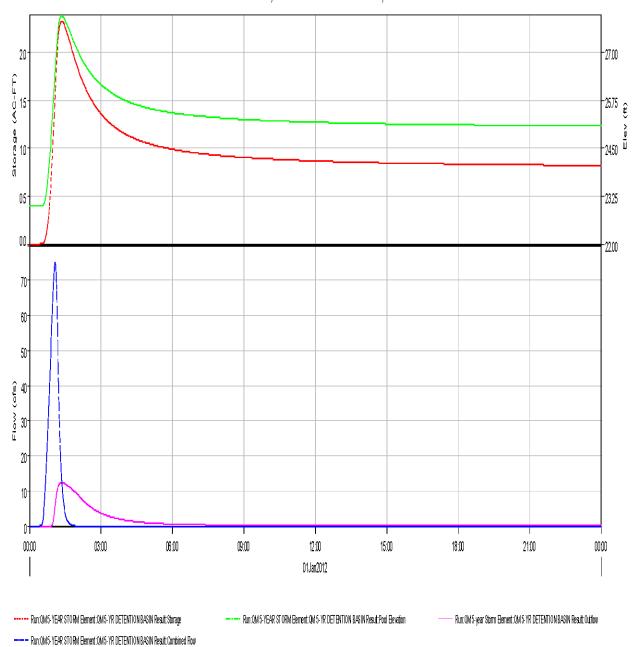

Pipe:	RCP culvert (end-section conforming to fill)
Diameter:	18 in
Length:	100 ft
Inlet Elevation:	25.00 ft
Outlet Elevation:	24.00 ft
Entrance Coefficient:	0.500
Slope:	0.010
Outlet Coefficient:	0.900
Mannings n:	0.013

#### **B.3 HEC-HMS Simulation:**

Simulation Run: QM 5-year Storm
Subbasin: QM Drainage Basin
Meteorologic Model: 5-year / 1 hour Storm
Control Specification: Control -24-hour

Computed Results			
Peak Inflow:	75.0 (cfs)	Time of Peak Inflow:	01:04
Peak Outflow:	<b>12.4</b> (cfs)	Time of Peak Outflow:	01:21
<b>Total Inflow:</b>	2.7 (ac-ft)	Peak Storage:	2.3 (ac-ft)
<b>Total Outflow:</b>	1.9 (ac-ft)	<b>Peak Elevation:</b>	27.9 (ft)

Reservoir "QM 5-yr Detention Basin" Results for Run "QM 5-year Storm"

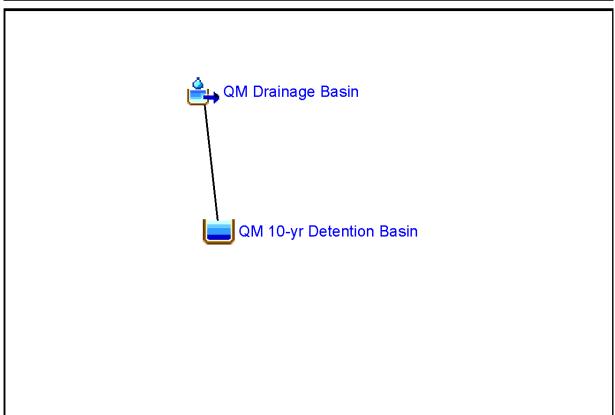

## 3. Quartermaster Site: 10-Year Storm Event

## **Project: Saipon Lagoon Restoration**

Basin Model: Quarter Master 10-yr Storm Dec 27 14:06:46 HST 2011

## A. Quartermaster Drainage Basin:

#### A.1 Basin Model:

Area: 109 ac (0.1703 mi<sup>2</sup>)

CN: 65

Tc: 10.7 min Rainfall 10-year/1 hour: 3.06 in

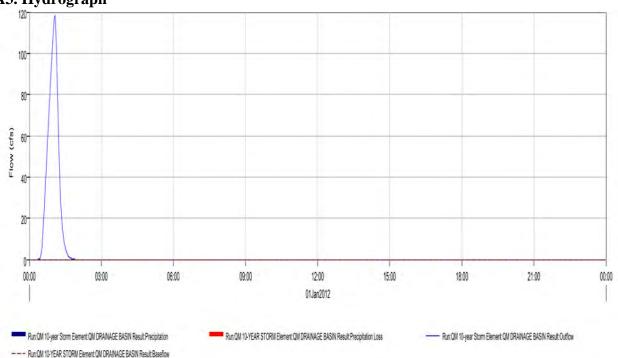

Loss Method: SCS Curve Number
Transform Method: SCS Unit Hydrograph

#### **A.2 HEC-HMS Simulation Results:**

Simulation Run: QM 10-year Storm
Subbasin: QM Drainage Basin
Meteorologic Model: 10-year / 1 hour Storm
Control Specification: Control -24-hour

Computed Results			
Peak Discharge:	118.5 (cfs)	Time of Peak Discharge:	01:04
<b>Total Precipitation:</b>	27.5 (ac-ft)	<b>Total Direct Runoff:</b>	4.7 (ac-ft)
<b>Total Loss:</b>	22.8 (ac-ft)	Total Baseflow:	0.0 (ac-ft)
<b>Total Excess:</b>	4.7 (ac-ft)	Discharge:	4.7 (ac-ft)

#### A3. Hydrograph

## **B. Quartermaster 10-Year Detention Basin:**

#### **B.1 Detention Basin Design:**

Elevation (ft)	Surf. Area (ac)	Increment Storage (ac-ft)	Cumulative Storage (ac-ft)
23.00	0.180	0.000	0.000
24.00	0.680	0.430	0.430
25.00	0.710	0.695	1.125
26.00	0.740	0.725	1.850
28.00	0.810	1.550	3.400
30.00	0.880	1.690	5.090
32.00	0.950	1.830	6.920

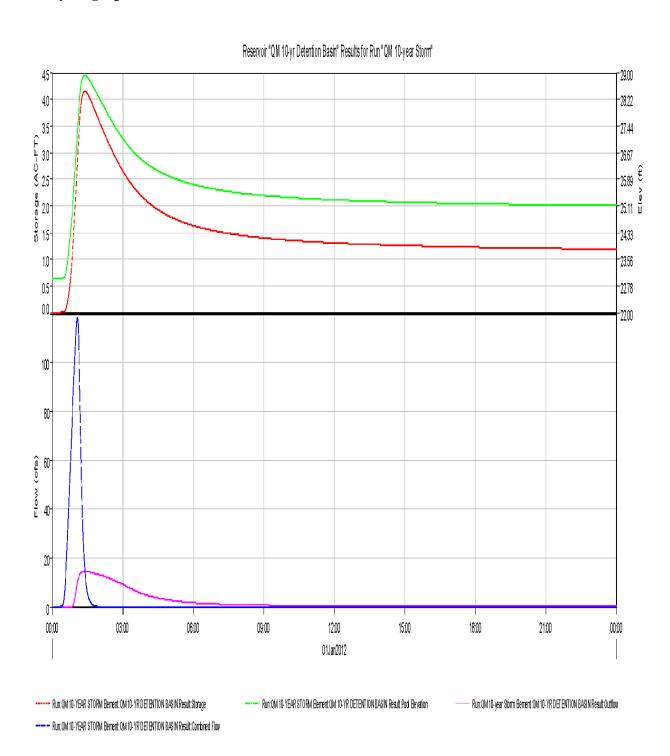

#### **B.2 Outlet Design:**

Pipe:	RCP culvert (end-section conforming to fill)
Diameter:	18 in
Length:	100 ft
Inlet Elevation:	25.00 ft
Outlet Elevation:	24.00 ft
Entrance Coefficient:	0.500
Slope:	0.010
Outlet Coefficient:	0.900
Mannings n:	0.013

#### **B.3 HEC-HMS Simulation:**

Simulation Run: QM 10-year Storm
Subbasin: QM Drainage Basin
Meteorologic Model: 10-year / 1 hour Storm
Control Specification: Control -24-hour

Computed Results			
Peak Inflow:	118.5 (cfs)	Time of Peak Inflow:	01:04
Peak Outflow:	14.5 (cfs)	Time of Peak Outflow:	01:23
<b>Total Inflow:</b>	4.7 (ac-ft)	Peak Storage:	4.2 (ac-ft)
<b>Total Outflow:</b>	3.5 (ac-ft)	Peak Elevation:	28.9 (ft)

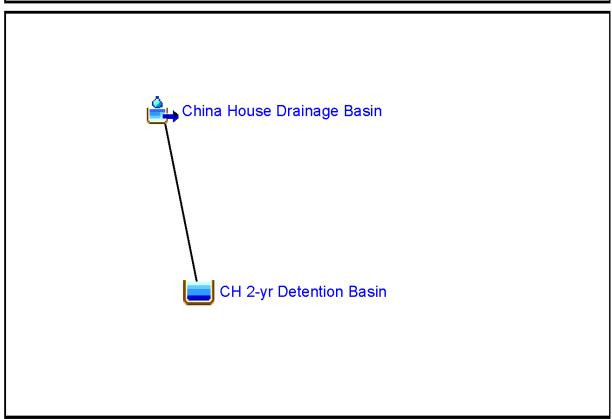

## 4. China House Site: 2-Year Storm Event

#### **Project: Saipon Lagoon Restoration**

Basin Model: China House 2-yr Storm Dec 27 13:50:14 HST 2011

## **A.China House Drainage Basin:**

#### A.1 Basin Model:

Area: 344 ac (0.5375 mi<sup>2</sup>)

CN: 68
Tc: 28.2 min
Rainfall 2-year/1 hour: 1.93 in

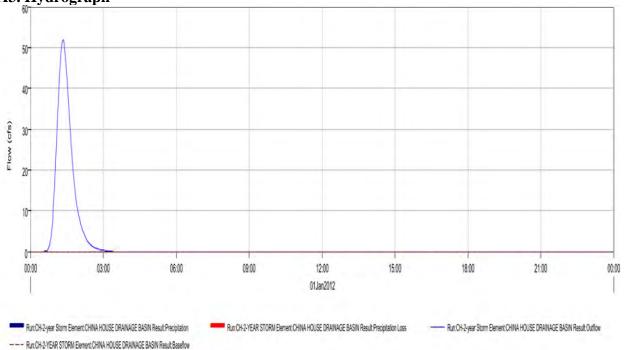

Loss Method: SCS Curve Number Transform Method: SCS Unit Hydrograph

#### **A.2 HEC-HMS Simulation Results:**

Simulation Run: CH 2-year Storm
Subbasin: CH Drainage Basin
Meteorologic Model: 2-year / 1 hour Storm
Control Specification: Control -24-hour

Computed Results			
Peak Discharge:	<b>51.9</b> (cfs)	Time of Peak Discharge:	01:20
<b>Total Precipitation:</b>	48.6 (ac-ft)	<b>Total Direct Runoff:</b>	3.0 (ac-ft)
Total Loss:	45.6 (ac-ft)	Total Baseflow:	0.0 (ac-ft)
<b>Total Excess:</b>	3.0 (ac-ft)	Discharge:	3.0 (ac-ft)

## **B. China House 2-Year Detention Basin:**

FINAL COORDINATION ACT REPORT

GARAPAN FLOOD CONTROL STUDY

SAIPAN, COMMONWEALTH OF

THE NORTHERN MARIANA ISLANDS

Description of Fraject Area. . . . .

UNITED STATES DEPARTMENT OF THE INTERIOR

FISH AND WILDLIFE SERVICE

HONOLULU FIELD OFFICE

July 1985

Prepared for the U.S. Army Engineer District, Honolulu

#### PREFACE

This report was prepared by John Ford, Andy Yuen, and Yvonne Ching, and is based on data gathered from existing literature and from Service field investigations conducted by Thomas Hablett, and Peggy Kohl from April 30 to May 11, 1979; and Gerald Ludwig, by John Ford and Commonwealth of the Northern Mariana Islands (CNMI) biologists on November 20, 1984. Data from Service forest bird surveys were provided by John Engbring, Supervisory Wildlife Project alternatives were provided by Rudy Biologist. Planning Branch. Engineering Division, Honolulu District. wish to acknowledge Drs. Tom Lemke and Thane Pratt Division of Fish and Wildlife for their excellent logistical and field support, and for their assistance in impact identification and analysis. We also gratefully thank Mr. Nicholas Guerrero, Director of the CNMI Department of Natural Resources.

#### DESCRIPTION OF PROJECT AREA

Garapan village is located on Saipan's west-central coast (Fig. 1). Prior to its nearly complete destruction during World War II, it was the principal population center on Saipan. Extensive rebuilding was completed after invasion by U. S. forces to facilitate administrative services and storage of war-related materials. Since the late 1940's, most of the U. S. military buildings have deteriorated or have been replaced by residential or light commercial buildings. Garapan is also the site of three major hotels. These are located along the white sand Micro Beach that borders Saipan Lagoon.

Inland from this coastal plain area, the land rapidly rises in a series of terraces that form Saipan's central limestone hill range. Mt. Tagpachau, Saipan's highest elevation (1,555 feet), is about 2.5 miles southeast of the village. The slopes of the geologically complex Tagpachau limestone ridge are dissected by steep ravines and occasional nearly vertical fault cliffs (Ref. 2). The narrow ravines and areas along the cliffs appear to have been shrub or forest vegetation in 1944. Many of the remaining terraces were cleared and cultivated in what appears to be sugar cane. Aerial photographs from 1978 show little evidence of farming along the slopes above Garapan.

There are no perennial streams within the project area. Deep valleys on the hillsides contain intermittent stream channels. The watershed within the project area covers 1.9 square miles (Ref. 15 and 16). Three wetland areas totalling about 32.1 acres in area are present within the Garapan watershed (Fig. 3). The largest is located in the American Memorial Park, just southwest of Tanapag Harbor (Fig. 3). This wetland covers an area of

Alternative C is similar to Alternative B except that the 1,800-foot long outlet channel would run along the Island Power Road (Fig. 5). The outlet channel would discharge into Saipan Lagoon south of the Hafa Adai Hotel. The channel would be trapezoidal in shape and would be riprap lined in areas of high water velocities. This alternative would affect 27 private lots and would require the relocation of 5 residences.

Alternative D has the same upland channel location as Alternative A (Fig. 6). This alternative would use the main Garapan wetland as a ponding basin for flood flows. The maximum storage capacity within the area is about 112 acre-feet over an area of 43 acres. The wetland would be graded to connect the ponds and create one large pond. The outflow channel would have an invert elevation set at +2.00 feet above mean sea level. The flood waters would discharge into Tanapag Harbor through four box culverts at Beach Road.

Alternative E has the same upland channel location as Alternative A (Fig. 7). However, the outlet channel is about 500 feet longer and detours around the main Garapan wetland. Flood waters would discharge into Tanapag Harbor.

Alternative F is a non-structural alternative that would require the permanent relocation of people and contents from flood prone areas or flood proofing buildings in the flood zone.

## TERRESTRIAL AND AQUATIC RESOURCES WITHOUT THE PROJECT

Previously cleared areas in the Garapan watershed have been revegetated with nearly pure stands of tangantangan (Leucaena leucocephala). The closed tangantangan canopy is 15-20 feet high and dense enough to inhibit extensive undergrowth in the more xeric hillside habitats. Ravines, however, have deeper soils that retain water better than the slopes. In these areas, undergrowth is more diversified with dense areas of grasses and tigre (Sansevieria trifasciata). Pago (Hibiscus tiliaceus), papao-apaka (Alocasia macrorrhiza) and kafu (Pandanus fragans) are also important constituents of the damper tangantangan areas. Dominant vegetation observed in the Garapan watershed is listed in Appendix 1.

The remaining forest vegetation is generally dominated by a mixture of introduced food or ornamental trees along with kafu, bamboo (Bambusa vulgaris), pago and ironwood (Casuarina litorea). Typical strand vegetation observed along the beach includes the beach morning glory (Ipomoea pes-caprae), pago, coconut (Cocos nucifera), ironwood and various grasses and shrubs. Urban vegetation includes many of the previously mentioned species as well as the flame tree (Delonix regia), a variety of garden vegetables and ornamental shrubs.

tidal flats along the shoreline of the lagoon. Lemke (1983, unpublished) listed six species of wading birds and 14 species of migratory shorebirds known from Saipan. Most of these species utilize the tidal flats adjacent to the American Memorial Park as resting and foraging habitat (Figure 16).

The Common Moorhen, Mariana Mallard (Anas oustaleti), Nightingale Reed Warbler, La Perouse's Megapode (Megapodius laperouse), and Vanikoro Swiftlet are listed endangered species. Although no endangered Micronesian Megapodes have been recorded from the Garapan watershed, a small population exists on Northern Saipan (Ref. 6). The upper Garapan watershed may be suitable habitat for this bird.

Marianas fruit bat (<u>Pteropus mariannus mariannus</u>) may be present in this area, but was not observed during the 1979 survey (Ref. 19). At one time, the endangered Mariana Mallard may have been found in the wetlands of the lower watershed; however, it is not known to reside there now.

Two Common Moorhens, a Black-Crowned Night Heron (Nycticorax nycticorax), two Mariana Fruit-Doves, two Nightingale Reed Warblers, and four Rufous Fronted Fantails were observed within the American Memorial Park wetland by Service and CNMI biologists during their survey on November 20, 1984.

A standing water body within the American Memorial Park provides a curious habitat for an estuarine fish. The small pond is linked with Tanapag Harbor by a drainage culvert during freshets. Apparently during these events, juveniles Megalops cyprinoides migrate into the pond and become trapped there by receding flows. At least 3 large adults (1.5 to 2 ft. in length) were observed in the shallow stagnant pond by Service and CNMI biologists in November 1984.

The nearshore marine environment within the study area can be generally described as sandy algae-sea grass (Enhalus acoroides and Halophila minor) habitat (Appendix 4) that is inhabited by at least 31 species of fish (Appendix 5) and an unknown variety of invertebrates (Ref. 1 and 19). The dock and shoreline substrate the southern boundary of the site is rubble that appears to have resulted from previous dredging and deterioration of the dock and shoreline seawall. The rubble along the outer edge of the basin is often exposed at low tide. This habitat (Fig. 8) (Table 1) is frequented by schools of cardinal fish, juvenile squirrel fish, damselfish, surgeonfish, rabbitfish, snappers, goatfish, an occasional eel and a variety of gobies and blennies (Appendix 5). Approximately 5% of the bottom is covered with living coral (Pocillopora damicornis). The bottom of the dredged area is sandy and is about 90% covered by a variety of algae and sea grasses.

Besides A. formosa, the most obvious invertebrates present were sea cucumbers (0.5 per m2) (Fig. 11) found on sandy substrate between coral growths. Species observed included Holothuria atra (most common), H. axiologa, H. edulis, Synapta maculata, and Bohadchia argus. Also present were unidentified invertebrates including crabs, a variety of sponges (Fig. 12), hydrozoan corals, bryozoans, and various worms.

These patch reefs apparently represent a unique environment within Saipan Lagoon (Fig. 4). Amesbury et al (Ref. 1) highly recommended preservation of this area because of the great diversity of fish species present. Interviews with boat operators that cater to tourist skin divers indicated that this spot is highly valuable to them because of its beauty, easy accessibility, and safety. Threatened Green Sea Turtles (Chelonia mydas) and Endangered Hawksbill Turtles (Eretmochelysimbricata) are occasionally observed on the reef off Garapan Dock (Ref. 21).

The northern site for the outlet channel near the American Memorial Park, is presently being used as a small boat harbor (Fig. 13). Its protected nature and proximity to hotels and to Managasan Island make it a prime site for tour boats, three of which were present during the 1979 survey. The site also serves as a mooring area for pleasure crafts.

Erosion of coral fill, in areas where sheet piling and wood retaining walls have deteriorated, has resulted in excessive turbidity. Poor visibility made the site difficult to survey during 1979.

Most of the substrate is sand, silt or rubble with occasional small corals. The bottom has an abundance of scrap metal and other debris, possibly artifacts from World War II. A wrecked World War II barge was present at the harbor entrance. A small boat harbor under construction at the time of the American invasion lies just north of the entrance. The remains of many landing crafts, reminders of World War II, are strewn across the nearby reef (Fig. 14) and around Garapan Dock.

Benthic marine vegetation is primarily <u>Halimeda</u> spp., <u>Padina</u> spp. with scattered <u>Sargassum</u> spp., <u>Halodule uninervis</u>, and <u>Enhalus acoroides</u> (Table 4). Deeper into the anchorage, murky water prevented an accurate estimation of vegetation cover, but <u>Halimeda</u> spp. and <u>Padina</u> spp. appeared to be dominant. Sea cucumbers, most likely <u>Holothuria</u> atra, were scattered across the bottom. The most common invertebrates along the shore were neritid and littorine mollusks.

A concern discussed in our draft 2(b) Coordination Act Report (February 25, 1985) was that the periodic introduction of flood waters into the marsh would reduce the salinity of the marsh waters and would negatively affect the wetland fern Acrostichum aureum and other components of the endangered Mariana Gallinule habitat.

Our report stated that the fern A. aureum flourishes in brackish water wetlands. The fern is not an obligate brackish water plant and flourishes in both freshwater and brackish water wetlands (D. Herbst, pers. comm.). This fern is tolerant of brackish water and has been found on the landward edge of mangroves swamps and in other mixohaline coastal wetlands.

The decrease in salinity of marsh waters would be temporary since the outflow time for 112 acre-feet would range from 3.7 to 5.0 hours. The reduction in salinity in the wetland resulting from the periodic flood water input would not have an adverse effect on  $\underline{\mathbf{A}}$ .  $\underline{\mathbf{aureum}}$  or the other vegetation components of the Garapan Marsh.

The use of the Garapan Marsh as a flooding basin does have the potential for introducing and bioaccumulating toxic substances in wetland fauna. Urban growth within the watershed may introduce petrochemicals, biocides, and other hazardous materials to the wetland.

Relative to the other alternatives, this alternative would result in a lower suspended sediment load being introduced into Tanapag Harbor because of the ponding and settling effects within the Garapan Marsh. This would result in a reduced impact to nearshore water quality and seagrass beds.

The removal of the asphalt fill areas in the Garapan wetland would require the construction of temporary causeways into the marsh. This construction would have temporary negative impacts on wetland vegetation and waterbird habitats. However, the removal of the asphalt fill would result in a net gain of wetland and waterbird habitat by removing fast lands within the wetland. From a wildlife standpoint, however, the removal of the fill is not necessary.

#### Alternative Plan E

In our draft 2(b) Coordination Act Report, the Service stated that the drainage channel alternative that skirted the marsh would have the least adverse impact on the Garapan wetland. An important qualifier to this recommendation was that the drainage channel be impervious to prevent sea water intrusion into the drainage channel and thereby increasing the salinity of the Garapan wetland. An impervious channel is necessary to maintain the existing water conditions within this wetland (Chuck Huxler, U.S. Geological Survey, pers. comm.).

#### U.S. FISH AND WILDLIFE MITIGATION POLICY

The Service's Mitigation Policy (Federal Register, Vol. 46, No. 15, January 23, 1981) was formulated with the intent to ". protect and conserve the most important and valuable fish wildlife resources while facilitating balanced development of the Nation's natural resources." The policy outlines internal guidance for Service staff and complements our participation under the Fish and Wildlife Coordination Act and National The Mitigation Policy does not apply Environmental Policy Act. to threatened or endangered species; specific requirements for these resources are covered in the Endangered Species Act of 1973 (50 CFR 17).

The policy focuses on the mitigation of habitat value, and on impacts to fish and wildlife populations. Our recommendations for mitigation/compensation will be based upon the habitat values adversely affected by the project, and not by loss of acreage alone. Our habitat valuations and recommendations will be based upon thorough consideration of all relevant biological data.

The Service considers the Garapan Marsh to be Resource Category 2. Under this category, the habitat to be impacted is of high value for the evaluation species and is relatively scarce or becoming scarce on a national basis or in the ecoregion setting. for this category is no net loss of in-kind mitigation goal habitat value. Specific planning goals include (1) physical modification of the replacement habitat to convert it to the same restoration or rehabilitation of previously type lost; (2) (3) increased management of similar replacement altered habitat; habitat so that the in-kind habitat value of the lost habitat is replaced; or (4) a combination of the above.

The evaluation species were various migratory waterfowl including the Green-winged Teal (Anas creca), Northern Pintail (A. acuta), Garganey (A. querquedula), Northern Shoveler (A. clypeata), and Tufted Duck (Aythya fuligula) and migratory shorebirds including the Lesser Golden Plover (Pluvialis dominica), Common Greenshank (Tringa nebularia), Marsh sandpiper (T. stagnatilis), Wood Sandpiper (T. glareola), Gray-tailed Tattler (Heteroscelus brevipes), Bar-tailed Godwit (Limosa lapponica), and others (J. Engbring, pers. comm.).

#### RECOMMENDATIONS

- a. From the mouth of the channel to Station 44 + 98, the drainage channel will be impervious to seawater intrusion. This impervious channel is necessary to maintain the existing water quality conditions within the Garapan Marsh.
- b. If the Corps determines that an impervious channel for Alternative E is economically unfeasible, the Service recommends the selection of Alternative D.

Re:

Biological Opinion (Log Number 1-2-95-F-01), PODCO GNW-95-008, Saipan Power Center, Chalan Laulau, Saipan, Commonwealth of the Northern Mariana Islands (CNMI).

#### Dear Lieutenant Colonel Elliott:

This report represents the biological opinion of the U.S. Fish and Wildlife Service (Service) in accordance with section 7 of the Endangered Species Act of 1973 (16 U.S.C. 1531-1544; Stat. 884), as amended, (Act) regarding potential impacts to the federally-listed, endangered Mariana common moorhen, Gallinula chloropus guami, and Nightingale reed-warbler, Acrocephalus luscinia, from the proposed issuance of Department of the Army (DOA) permit PODCO GNW-95-008. The Corps of Engineers (Corps) proposes to authorize J. C. Tenorio Enterprises, Inc. to fill 0.88 hectares (ha) [2.17 acres (ac)] of wetland in Chalan Laulau, Saipan, CNMI.

This biological opinion is based upon 1) review of the information presented in the permit application and proposed mitigation plan for the project, 2) information provided in the 1992 Recovery Plan for the Mariana Common Moorhen, 3) literature published on moorhens and reed-warblers, and 4) information gained during site visits to the project area.

The Corps requested initiation of section 7 consultation for the proposed permit action in a letter dated August 25, 1994, received by the Service on August 29, 1994. Service biologists conducted inspections of the project site and mitigation area on September 15 and November 2, 1994, with a biologist from the CNMI Division of Forestry and Wildlife (CNMI DFW). The log number for this consultation is 1-2-95-F-01. A complete administrative record of this consultation is on file in the Service's Pacific Islands Office (PIO) in Honolulu, Hawaii.

#### **BIOLOGICAL OPINION**

It is the biological opinion of the Service that issuance of DOA permit GIN94-021, as described below, is not likely to jeopardize the continued existence of the Mariana common moorhen or Nightingale reed-warbler. Some level of incidental take for these species is anticipated, and the Service has specified reasonable/prudent measures and terms/conditions to minimize the impact of any takings.

# Description of the Proposed Action

The Corps proposes to issue a Nationwide Permit, PODCO GNW-95-008, to authorize J. C. Tenorio Enterprises, Inc. (the applicant) to fill 0.88 ha (2.17 ac) of wetlands to facilitate the development of the Saipan Power Center in the Chalan Laulau District along the west central coast of Saipan (Figure 1). The purpose of the project is to provide retail, financial, and entertainment facilities for the people of Saipan. These facilities include two retail buildings totaling 8,379 square (sq) meters (m) [90,100 sq feet (ft)], a movie theater that is 1,860 sq m (20,000 sq ft), a financial building that is 558 sq m (6,000 sq ft), and a restaurant that is 1,116 sq m (12,000 sq ft).

The project site is located on private property and is generally bounded by Beach Road to the west, Chalan Pale Arnold to the east, and Chalan Monsignor Guerrero (Airport Road) to the southwest (Figure 2). The project site encompasses 7.18 ha (17.73 ac) that are zoned as autourban and includes 2.37 ha (5.84 ac) of wetlands and 4.81 ha (11.86 ac) of uplands. Project-site wetlands are dominated by karriso, *Phragmites karka*, and pago, *Hibiscus tiliaceus*. Upland habitat at the project site includes scrubby secondary forest dominated by tangantangan, *Leucaena leucocephela*, and limestone forest dominated by *Barringtonia asiatica* with *Ficus prolixa* and *Hernandia nymphaeifolia*.

The project includes a conceptual wetland mitigation plan to offset the loss of 0.88 ha (2.17 ac) of wetlands. The mitigation plan involves wetland creation from project-site uplands [0.88 ha (2.17 ac)] and enhancement of the remaining 1.49 ha (3.68 ac) of project-site wetlands. The resulting created/enhanced mitigation wetland will be 2.37 ha (5.84 ac) in size (Figure 3).

The mitigation wetland will have an irregular bottom contour and be excavated to a depth that will insure that the site retains open water areas during the dry season. It will also include an island or islands and a deep moat. The mitigation wetland will be planted with sedges along the littoral zone and submergents in the open water zone and will include a vegetated buffer of karriso. These features are included in the design of the mitigation wetland to provide year-round nesting and foraging habitat for Mariana common moorhens.

Additional features included in the conceptual mitigation plan to insure that the wetland is maintained primarily as moorhen habitat include (1) the removal of karriso if it covers more than 20% of the wetland, (2) the removal of encroaching woody vegetation, (3) the control of submergent vegetation, and (4) documenting and monitoring of vegetation growth and control.

#### Biology and Population Status of the Species

#### a. Mariana Common Moorhen

Unless otherwise referenced, the following information on the status and habitat requirements of the Mariana common moorhen is taken from the Recovery Plan for the Mariana Common Moorhen (USFWS, 1992), unpublished field notes, published literature, and field surveys.

The Mariana subspecies of the common moorhen is endemic to the Mariana Archipelago. Adults are about 35 cm (14 in) in length, have slate-black plumage, red bills and frontal shields, white undertail coverts, white bands on their flanks, and olive-green legs. Immature birds have brown plumage, small frontal shields, and brownish bills and legs. Chicks have black plumage and black legs (Ritter, 1994).

Mariana common moorhens inhabit natural and human-made seasonal and permanent fresh water and occasionally brackish water wetlands. Moorhens also make use of recently flooded pastures and newly created wetlands (Stinson, 1993; Ritter and Sweet, 1993). Moorhens are secretive and seem to prefer wetlands with equal areas of open water and vegetation. They are opportunistic feeders and feed primarily on plant and animal matter in or near the water, including algae, seeds, and aquatic insects and their larvae.

Reproductive and nesting characteristics of the Mariana common moorhen have been described (Ritter, 1994) and are similar to those of more temperate region moorhen subspecies (Howard 1940; Wood, 1974). Active Mariana common moorhen nests have been found in all months of the year [USFWS unpubl. data, CNMI DFW (Tinian) unpubl. data, CNMI DFW (Saipan) unpubl. data, Guam Department of Aquatic and Wildlife Resources (DAWR) unpubl. data]. Nests are typically constructed within emergent vegetation but also may be placed on beds of submergent vegetation or protruding stumps and logs. Artificial platforms such as floating boards may also be used as nest sites (USFWS unpubl. data; Guam DAWR unpubl. data; Ritter, 1994). Average clutch size for the Mariana common moorhen is approximately six eggs (Guam DAWR unpubl. data), and incubation requires 18-22 days (Brown, 1940; Wood, 1974; Byrd and Zeillemaker, 1981).

The Mariana common moorhen was listed as endangered on August 27, 1984 (49 FR 33885) (USFWS, 1994). Habitat loss was identified as the primary factor influencing the decline of this subspecies (USFWS, 1992). Other factors potentially affecting moorhen populations in the Mariana Islands include competition with tilapia (Stinson et al., 1991), nest loss due to flooding (Ritter, 1994; USFWS unpubl. data), destruction of nesting habitat by feral ungulates (Guam DAWR unpubl. data), hunting pressure, and predation by the brown tree snake and feral cats and dogs.

Present populations of Mariana common moorhens are found on Guam, Tinian, and Saipan. Archaeological excavations indicate the presence of the moorhen on Rota between 1,500-2,000 years ago (Butler, 1988). The population on Pagan is likely extinct due to volcanic activity

and feral ungulates (Stinson et al., 1991). No moorhens or wetlands exist on any of the other Mariana Islands.

Historically, moorhen populations on Guam were considered numerous and widely distributed. Moorhens were reported from fresh and brackish water wetlands, fallow rice paddies, and cultivated taro patches (Hartert, 1898; Seale, 1901; Baker, 1951; Beaty, 1967). Baker (1951) found large numbers of moorhens along the Ylig River and in the Agana Swamp. The most recent surveys (Ritter, 1989; Stinson et al., 1991) recorded moorhens at 18 wetlands on Guam, including 15 that are human-made.

Wetland habitats in the Northern Mariana Islands are not as diverse or abundant as those on Guam. Nevertheless, moorhen populations were considered abundant in high quality habitat such as Lake Hagoi on Tinian and Lake Susupe on Saipan (Stott, 1947; Marshall, 1949). The most recent surveys recorded moorhens at nine wetlands on Saipan (Stinson et al., 1991) and four wetlands on Tinian (USFWS unpubl. data).

The estimated total population of moorhens is 300-400 birds, including 100-125 birds on Guam, 100 birds on Saipan, and 75 birds on Tinian. An assessment of habitat loss and reviews of the literature and field notes indicate that the moorhen population in the Mariana Islands has been reduced by 36-52% in this century (Stinson et al., 1991).

#### b. Nightingale Reed-warbler

Unless otherwise referenced, the following information on the status and habitat requirements of the Nightingale reed-warbler is taken from unpublished field notes, published literature, and field surveys.

Three subspecies of the Nightingale reed-warbler are found in the Mariana Islands. A. l. luscinia is likely extinct on Guam but still found on Saipan and Alamagan (Reichel et al., 1992). The subspecies A. l. nijoi on Aguijan was thought to be extinct, but was recently rediscovered (Craig, 1992). The subspecies A. l. yamashinae known from Pagan is likely extinct (Reichel et al., 1992). Nightingale reed-warblers are not found on Rota or Tinian, but other subspecies are found in Micronesia on the islands of Chuuk, Pohnpei, and Nauru.

Reed-warblers are slender, long-billed, rather non-descript brownish/buff birds that inhabit dense vegetation around wetland/upland ecotones or other semi-open areas and second-growth forests. Reed-warblers feed on insects and their larvae, lizards, snails, and spiders (Seale, 1901; Marshall, 1949). Nightingale reed-warblers are territorial, and individual males are known to defend an area approximately 9000 sq m. Males have high site fidelity and appear to be monogamous while females may exhibit low mate fidelity between years. The breeding season is approximately January-June. (Craig, 1992).

The Nightingale reed-warbler was listed as an endangered species in 1970 (35 FR 8495 and 35 FR 18320) (USFWS, 1994). Loss of wetlands and understory vegetation by volcanic activity, land development, and feral ungulates; fires in wetlands; pesticides; and predation are cited as the primary reasons for these extinctions (Reichel et al., 1992).

Nightingale reed-warblers are still found on Alamagan where the conservative estimate of the population is 350 pairs (Reichel et al., 1992). The most recent surveys of reed-warblers on Saipan indicate that the birds are common over much of the island and are associated with karriso-dominated wetlands, native limestone forests, and habitats characterized by a dense understory, including wetland/upland ecotones and mixed tangantangan/grassland habitats (Craig, 1992; Reichel et al., 1992). Engbring et al. (1986) recorded 578 reed-warblers on Saipan during eight-minute counts. He estimated the average density of reed-warblers on Saipan to be 46 birds/sq km and the total population to be 4,867 birds.

#### Environmental Baseline

The environmental baseline describes the status of the species and factors affecting the environment of the species or critical habitat in the proposed action area contemporaneous with the consultation in process. The baseline includes State, local, and private actions that affect a species at the time the consultation begins. Unrelated federal actions that have already undergone formal or informal consultation are also a part of the environmental baseline. Federal actions within the action area that may benefit listed species or critical habitat are included in the environmental baseline.

#### a. Mariana Common Moorhen

Project-site wetlands are included in a complex of wetlands locally identified as the Chalan Laulau wetlands. The Chalan Laulau wetlands are generally dominated by dense stands of karriso and pago with limited open water areas. Nevertheless, smaller areas supporting an interspersion of open water and emergent and floating aquatic vegetation can be found along the outside edges of these karriso/pago-dominated wetlands. These small open areas represent suitable habitat for moorhens and are probably more frequently used by moorhens as sites for foraging and nesting than the dense karriso/pago dominated areas.

One such area, located outside the project boundary but contiguous to the project's mitigation area, was identified in the conceptual mitigation plan and visited by Service and CNMI DFW biologists on two occasions. During a September 15, 1994, visit, the area was dry, and no moorhens were observed using the wetland. However, on November 2, 1994, the site was flooded and approximately 0.3-0.6 m (1-2 ft) of surface water was present. One adult and three juvenile moorhens were observed during the November site visit. Based on these observations, it is likely that this area was used as nesting habitat during the 1994 rainy season.

To the best of our knowledge, no prior moorhen surveys have been conducted in wetland areas adjacent to or within the project site. Based on information gained during site visits and review of aerial photographs of the project-site wetlands, the Service estimates that less than one acre of wetland habitat is presently suitable for moorhen use within the project boundary. Since project-site wetlands are dominated by karriso and pago and have very limited open water areas, it is likely that these wetlands do not provide suitable nesting habitat for Mariana common moorhens. However, since moorhens have been observed within the contiguous wetland located just outside of the project boundary, they likely use project-site wetlands as escape cover and seasonally for foraging. Moorhens are more likely to use project-site wetlands during the rainy season when ponded areas are present and provide foraging habitat.

#### b. Nightingale Reed-warbler

Project-site habitats include both wetlands [2.37 ha (5.84 ac)] and uplands [4.81 ha (11.86 ac)]. Wetlands are dominated by karriso and pago. Uplands include a small area of *Barringtonia* forest but are predominantly scrubby secondary forest dominated by tangantangan. Transitional habitat comprised of both wetland and upland plant species occurs between the upland and wetland, habitats.

Project-site habitats are contiguous with adjacent offsite habitats from the north to the southeast. Offsite habitats include *Barringtonia* and scrubby secondary forest as well as karriso and pago. The remainder of the surrounding land is commercially developed.

The entire project site represents reed-warbler habitat. Information provided in the permit application states that one Nightingale reed-warbler was recorded at the project site in January 1994. The bird was observed in the vegetation margin between the wetlands and *Barringtonia* forest. During a site visit on November 2, 1994, Service biologists observed that the adjacent wetland and upland habitats also represent potential foraging and nesting habitat for reed-warblers.

Engbring et al. (1986) estimated the average density of Nightingale reed-warblers as 46 birds/sq kilometers (km) on Saipan. Using this data, we estimate that the project site currently supports approximately four Nightingale reed-warblers. This number represents approximately 0.08% of the estimated population of reed-warblers on Saipan.

# Effects of the Action on Listed Species

#### a. Mariana Common Moorhen

The primary concerns of the Service with regard to the effects of the permit action on Mariana common moorhens are (1) the loss of approximately 0.88 ha (2.17 ac) of wetland and (2) the potential for recurring destruction of moorhen nests and eggs and mortality of moorhen chicks during maintenance activities at the mitigation site.

Approximately 0.88 ha (2.17 ac) of existing karriso-dominated wetland will be filled to facilitate the development of the Saipan Power Center. These wetlands are likely used by moorhens as escape and foraging habitat, particularly during the rainy season when ponded areas are present. Habitat loss is a primary reason for the decline of the Mariana common moorhen. Incremental wetland losses represent permanently removed habitat, which, if otherwise protected and managed, could contribute to the recovery goals of the species. Therefore, even the loss of small areas of the Chalan Laulau wetlands represents an adverse effect to Mariana common moorhens.

Nevertheless, any moorhens using project-site wetlands at the time of construction would likely disperse to the adjacent wetland habitat. Therefore, no harm to moorhens is anticipated as a result of construction activities associated with the filling of project-site wetlands.

The development of the Saipan Power Center includes a conceptual mitigation plan to offset the loss of project-site wetlands. Enhancement of existing wetlands and creation of wetland from uplands will result in 2.36 ha (5.84 ac) of managed and permanent open water wetland habitat at the project site. The development of the mitigation wetland will occur concurrently with the filling activities. Based on the proposed characteristics of the mitigation wetland (open water, vegetation, management) and the size of the mitigation site, it is anticipated that the mitigation wetland will provide year-round nesting and foraging habitat for an estimated two breeding pairs of Mariana common moorhens.

Recurring harassment of moorhens and potential loss of nests/eggs/chicks is anticipated to occur during periodic maintenance activities at the mitigation site. Adult and juvenile moorhens present within the mitigation wetland when these activities are initiated will likely be harassed by increased noise from machinery and human activity. These disturbance factors may disrupt normal foraging and nesting behaviors and cause moorhens to temporarily disperse from or to avoid using the mitigation wetland. If the maintenance activities occur when moorhen are nesting, then the loss of nests/eggs and chicks would be anticipated, as well as loss of reproductive capability of displaced adults that are not able to immediately establish new breeding territories. Harm and harassment of moorhens is more likely to occur during the rainy season when available nesting and foraging habitat is increased.

## b. Nightingale Reed-warbler

The primary concerns of the Service with regard to the effects of the permit action on the Nightingale reed-warbler are (1) the loss of reed-warbler habitat and (2) the potential loss of nests with eggs and/or chicks during construction of the project and the mitigation wetland.

Approximately 7.18 ha (17.73 ac) of potential reed-warbler habitat will be destroyed to facilitate construction of the Saipan Power Center. This includes (a) the loss (filling) of 0.88 ha (2.17 ac) of karriso wetland, (b) the loss (clearing) of 3.92 ha (9.60 ac) of Barringtonia and scrubby secondary forest for development of the Power Center, and (c) the conversion of

1.49 ha (3.67 ac) of karriso wetland and 0.88 ha (2.17 ac) of scrubby secondary forest to emergent vegetation/open water habitat to develop the mitigation wetland.

Based on observations made during site visits to the project area, reed-warbler habitat is known to exist on adjacent lands. The Service believes that any adult and juvenile reed-warblers displaced by the project could successfully disperse to unoccupied habitat within these adjacent areas. Therefore, no harm to adult or juvenile reed-warblers is anticipated as a result of construction activities associated with the filling of the project-site wetlands, clearing of upland forests, or construction of the mitigation wetland.

Harm to reed-warblers is more likely to occur if filling, clearing, and conversion activities are conducted during the breeding season (January-June). Loss of nests/eggs and chicks would be anticipated, as well as potential loss of reproductive capability of displaced adults that are not able to immediately establish new breeding territories.

#### Cumulative Effects

Cumulative effects include the effects of future State, local, or private actions that are reasonably certain to occur in the area considered in this biological opinion. Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the Act. The Service has not identified any cumulative effects in the project area that may impact Mariana common moorhen or Nightingale reed-warblers.

## Biological Opinion of the Service

After reviewing the current status of the Mariana common moorhen and the Nightingale reedwarbler, the environmental baseline of the species in the action area, the effects of the proposed action, including cumulative effects, it is the Service's biological opinion that issuance of PODCO GIN94-021 to facilitate the development of the Saipan Power Center, as proposed, is not likely to jeopardize the continued existence of the Mariana common moorhen or the Nightingale reed-warbler. No critical habitat has been designated for these species; therefore, none will be affected.

#### INCIDENTAL TAKE

Sections 4(d) and 9 of the Act, as amended, prohibit the taking (harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct) of a listed species of fish and wildlife without a special exemption. Harm is further defined to include significant habitat modification or degradation that results in the death or injury to listed species by significantly impairing behavioral patterns, such as breeding, feeding, or sheltering. Harass is defined as actions that create the likelihood of injury to listed species to such an extent as to significantly disrupt normal behavior patterns which include, but are not

limited to, breeding, feeding, or sheltering. Under the terms of section 7(b)(4) and section 7(0)(2), taking that is incidental to and not intended as part of the agency action is not considered a prohibited taking provided that such taking is in compliance with the terms and conditions of this incidental take statement. The measures described below are non-discretionary and must be implemented by the Corps or become binding conditions of any grant or permit issued to the applicant, as appropriate, in order for the exemption in section 7(0)(2) to apply.

The Corps has a continuing duty to regulate the activity that is covered by this incidental take statement. If the Corps fails to adhere or require the applicant to adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to the permit or grant document, the protective coverage of section 7(0)(2) may lapse. This exemption only applies to the Endangered Species Act, as amended, and does not supersede the requirements of the Migratory Bird Treaty Act.

#### Amount or Extent of Take

#### a. Mariana Common Moorhen

Incidental take in the form of harassment of adult and juvenile moorhens and potential harm to moorhen nests/eggs and chicks may occur during maintenance activities at the mitigation wetland. Based on the above information, the following levels of incidental take are anticipated:

- 1. Harassment of four adult moorhens and four juvenile moorhens during as-needed maintenance activities at the mitigation wetland.
- 2. Loss of three moorhen chicks and one moorhen nest per maintenance event at the mitigation wetland.

# b. Nightingale Reed-warbler

Incidental take in the form of harm to adult Nightingale reed warblers and their nests with eggs and/or chicks may occur as a result of loss and modification of upland and wetland habitats within the project area.

Based on the above information, the following levels of incidental take are anticipated:

- 1. Loss of 7.18 ha (17.73 ac) of foraging and potential nesting habitat for Nightingale reed-warblers.
- 2. Loss of one Nightingale reed-warbler nest with eggs/chicks as a result of forest and wetland habitat loss and modification within the Saipan Power Center development site.

#### Effect of the Take

#### a. Mariana Common Moorhen

The Service has determined that this level of impact is not likely to result in jeopardy to the Mariana common moorhen because (1) no harm to adult or juvenile moorhens is anticipated, (2) the mitigation wetland will provide year-round foraging and nesting habitat for moorhens and offset the loss of wetland habitat filled for project construction, and (3) the applicant has committed to provide periodic maintenance at the mitigation wetland, which will provide stable moorhen habitat and promote the recovery of this subspecies.

#### b. Nightingale Reed-warbler

The Service has determined that this level of impact is not likely to result in jeopardy to the Nightingale reed-warbler because (1) no harm to adult or juvenile reed-warblers is anticipated and (2) the potential loss of nests with eggs and/or chicks due to filling of wetland habitats and conversion of wetland and upland habitats represents a one time loss in reproduction for the birds in the project area.

#### Reasonable and Prudent Measures

The Service believes that the following reasonable and prudent measures are necessary and appropriate to minimize take:

- 1. The Corps shall insure that the applicant fully complies with the special conditions of the permit.
- 2. The Corps shall require the applicant to minimize the destruction of moorhen and reed-warbler nests/eggs and mortality of moorhen and reed-warbler chicks during (1) filling of the existing wetland, (2) enhancement and creation of the mitigation wetland, and (3) maintenance activities at the mitigation wetland.
- 3. In order to preserve the remaining reed-warbler habitat at the project site, the Corps shall require the applicant to maintain the vegetation margin between the wetland and the development in its existing condition by not landscaping this area.

## Terms and Conditions

In order to be exempt from the prohibitions of section 9 of the Act, it is mandatory that the Corps comply with the following terms and conditions, which implement the reasonable and prudent measures described above:

- 1. The Corps shall require the applicant to have a qualified biologist conduct moorhen and reed-warbler censuses and nest searches within the project-site wetlands prior to filling and conversion activities. Results of the surveys shall be provided to the CNMI DFW and the PIO. Resource agencies will provide additional instructions for protecting any nests/eggs/chicks identified.
- 2. The Corps shall require the applicant to instruct contractors to avoid destroying active moorhen and reed-warbler nests with eggs. Contractors observing nests in any work area are to notify the Saipan DFW (670/233-9095) and the PIO (808/541-3441) for additional instructions for protecting nests/eggs/chicks.

The second secon

- 3. The Corps shall require the applicant to conduct the filling of wetlands for development of the Saipan Power Center during the middle to latter portion of the dry season, if possible.
- 4. The Corps shall require the applicant to conduct wetland enhancement and creation of the mitigation site during the middle to latter portion of the dry season, if possible.
- 5. The Corps shall require the applicant to schedule maintenance activities within the mitigation wetland during the middle to latter portion of the dry season.
- 6. The Corps shall require the applicant to have a qualified biologist conduct a moorhen census and nest search within the mitigation wetland prior to each maintenance event. Results of the surveys shall be provided to the CNMI DFW and the PIO. Resource agencies will provide additional instructions for protecting any nests/eggs/chicks identified.
- 7. The Corps shall require the applicant to instruct contractors working within the mitigation wetland to avoid destroying active moorhen nests/eggs or harming chicks. Contractors observing nests/eggs or chicks in any work area are to notify the CNMI DFW (670/233-9095) and the PIO (808/541-3441) for additional instructions for protecting nests/eggs/chicks.
- 8. The Corps shall inform the applicant that the mitigation plan is conceptually approved by the Service, but the applicant should, within budgetary confines, implement any additional measures recommended by the Service and CNMI DFW to modify or rectify the mitigation wetland for the benefit of endangered species in the area.

The reasonable and prudent measures, with their implementing terms and conditions, are designed to minimize the impacts of the incidental take that might otherwise result from the proposed action. With implementation of these measures, the Service believes that harassment of moorhens and reed-warblers will be minimized and no moorhens or reed-warblers will be

harmed during maintenance activities at the mitigation wetland. If, during the course of the action, the amount or extent of incidental take is exceeded, such incidental take would represent new information requiring review of the reasonable and prudent measures provided. The Corps must immediately provide an explanation of the causes of the taking and review with the Service the need for possible modifications of the reasonable and prudent measures.

Disposition of Sick, Injured, or Dead Individuals

The Service's Law Enforcement office in Guam (671/472-7146) or the CNMI DFW (760/233-9095) should be notified immediately for care instructions regarding any sick or injured Mariana common moorhens or Nightingale reed-warblers found within the project area. If dead individuals are found, the Service's Law Enforcement Office in Guam or the CNMI DFW should be notified within one working day. Dead moorhens or reed-warblers should be wrapped in aluminum foil and refrigerated (dead birds should not be wrapped in plastic or placed in a freezer). The Service's Law Enforcement Office or the CNMI DFW will provide further instructions on the proper disposal of the animals, including shipping requirements to facilities to determine cause of death, if the cause is not known. The Service's Law Enforcement Office in Guam, the PIO in Honolulu, and the CNMI DFW should be provided with a written report describing the events surrounding the demise or injury of the species, if known.

# CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of the Act directs Federal agencies to use their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to develop information. The recommendations provided here relate only to the proposed action and do not necessarily represent complete fulfillment of the Service's Section 7(a)(1) responsibilities for the species.

Suitable moorhen habitat is limited in the Mariana Islands and loss of habitat is cited as the primary reason contributing to the decline of this subspecies. Protection of existing wetlands and long-term management of vegetation to create more open water habitats would promote the recovery of moorhens. The Service recommends that the Corps encourage the applicant to consider the acquisition of the wetland immediately adjacent (southwest) to the mitigation site. This wetland currently provides excellent nesting and foraging habitat for moorhens. The Service is willing to provide technical assistance to J. C. Tenorio Enterprises, Inc. in designing a wetland enhancement plan and developing wetland management objectives for the benefit of the endangered Mariana common moorhen and other wetland-dependant species at this wetland. This action would represent the initial effort by a private wetland owner in the CNMI to acquire additional wetland area and manage it for the benefit of moorhens.

Incremental development of scrub/tangantangan upland represents loss of existing and potential Nightingale reed-warbler habitat. The Service is concerned that the loss of upland habitat for wetland creation that benefits moorhens may negatively impact reed-warblers. The Service recommends that in the future the Corps require applicants to conduct thorough reed-warbler surveys in upland habitats where mitigation actions are being considered.

In order for the Service to be kept informed of actions that either minimize or avoid adverse effects or that benefit listed species or their habitats, the Service requests notification of the implementation of any conservation recommendations.

#### CONCLUSION

This concludes formal section 7 consultation on this action. As required by 50 CFR 402.16, reinitiation of formal consultation is required if (1) the amount or extent of incidental take is exceeded, (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion, (3) the agency action is subsequently modified in a manner that causes an adverse effect to the listed species or critical habitat that was not considered in this opinion, or (4) a new species is listed or critical habitat designated that may be affected by this action. In instances where the amount or extent of incidental take is exceeded, any operations causing such take must cease pending reinitiation.

If you have questions concerning any of the information contained in this biological opinion, please contact Fish and Wildlife Biologists Michael Ritter (808/541-3441) or Dianne Bowen (808/541-2749).

Sincerely,

**Enits** 

Brooks Harper Field Supervisor

**Ecological Services**

Subject: Request for listed species regarding the Saipan Lagoon Aquatic Ecosystem Restoration Plan

To Whom It May Concern:

Thank you for your request for listed species. The species of concern in the CNMI, and federally listed endangered species are as follows;

Nightingale Reed-Warbler (Acrocephalus luscinia) Mariana Common Moorhen (Gallinula chloropus guami) Micronesian Megapode (Megapodius laperouse) Mariana Fruit Bat (Pteropus mariannus) Mariana Swiftlet (Aerodramus bartschi), Rota Bridled White-eye (Zosterops rotensis) Mariana Crow (Corvus kubaryi)

Note, not all species are found on each island. DFW coordinates with the United State Fish and Wildlife Service (USFWS) on all matters concerning federally listed species. In all cases of development, surveys are necessary to ensure that there is no impact to these species of concern or to determine necessary mitigation measures.

Once specific areas for development are flagged and appropriate permit applications and survey requests completed, DFW will discuss surveys for a project area. If there are any questions please contact the wildlife division at 664-6012.

Sincerely,

Arnold I. Palacios DFW Director

CRM USFWS DEQ

#### DEPARTMENT OF THE ARMY

U.S. ARMY CORPS OF ENGINEERS, HONOLULU DISTRICT FORT SHAFTER, HAWAII 96858-5440

October 30, 2012

REPLY TO ATTENTION OF:

Environmental Programs Branch Programs and Project Management Division

Ms. Merti Kani Acting Director Division of Historic Preservation Department of Community and Cultural Affairs Commonwealth of the Northern Mariana Islands P.O. Box 500090 Saipan MP 96950

Dear Ms. Kani:

The U.S. Army Corps of Engineers, Honolulu District (USACE-POH), is proposing an undertaking to restore the Saipan Lagoon aquatic ecosystem as closely as possible to its natural state. The lagoon is located on the western shoreline of the island of Saipan, Commonwealth of the Northern Mariana Islands (CNMI). The project area extends from the Quartermaster Road north to just past the Fishing Base in Garapan and it includes the entire watershed that contributes ground and surface water runoffs to the approximately two-mile length of shoreline as well as to the adjacent offshore lagoon area out to the fringing coral reef (See enclosed Figures 1 through 3). Restoration alternatives are being formulated with the goal of restoring the ecosystem to be self-sustaining in the substantially modified environment. The purpose of this letter is to initiate Section 106 coordination and consultation with your office in compliance with the National Historic Preservation Act of 1966, as amended, and implementing regulations 36 CFR Part 800 (NHPA) for the proposed undertaking.

Three alternative drainage detention basin sites are being considered to achieve the overall project restoration goal. The proposed locations for the three retention basins are at the China House (Alternative 1), the Quartermaster Site (Alternative 2), and the Cock Fight Arena (Alternative 3) (See enclosed Figure 4). Three sizes of the basin are being designed for each of the three sites, corresponding to the expected influx of water during a two-year, five-year, and ten-year rainfall event; there are a total of nine possible scenarios for the three different site locations.

Background research of the project location identified archaeological remains that included features attributed to the Japanese and American World War II periods in the history of Saipan as well as subsurface prehistoric pottery-bearing cultural deposits. Garapan is also known for the presence of human burial remains, which were recorded during the development of shopping areas along Garapan's main thoroughfare. The Quartermaster Site location appeared to have

been extensively used as a warehouse area by the military during the World War II era while the Cock Fight Arena consisted of an abandoned modern-day quarry. A preliminary reconnaissance level walk-through survey of the three locations was conducted in 2003 by a two-person USACE-POH archaeological team who identified no surface archaeological sites; however, three concrete warehouse remnants were located in the Quartermaster Site area. All superficial structural remains of the warehouses had been completely destroyed and the warehouses themselves lacked any integrity and they were determined not eligible for nomination to the National Register of Historic Places.

The exact location and design of the three retention basins have yet to be determined. In any case, their locations shall be re-surveyed to ensure that no cultural resources are present anywhere near those areas. Because of the potential that subsurface cultural deposits, including human burial remains, may be present in the project areas, all construction activities shall be monitored by a qualified archaeologist in compliance with the Secretary of the Interior's Standards and Guidelines and who has at least two years of continuous archaeological experience working in the CNMI. Prior to the start of any ground breaking construction activities associated with this project, an Archaeological Monitoring Plan (AMP) shall be compiled by the archaeologist and submitted to your office for review and comments before its finalization. A full archaeological report documenting the results of the archaeological monitoring shall also be submitted at the end of all construction activities to your office for your library and files.

Based on our knowledge of the project area, we believe that the presence of a qualified archaeologist during construction will ensure the protection of potentially significant cultural resources including human burial remains that may be present subsurface within the project's area of potential effect. The USACE-POH, therefore, is of the opinion that, with the presence of a qualified archeologist monitor during all new ground breaking construction activities as well as the submittal of a final AMP and post-monitoring archaeological report to your office, a determination can be made that the proposed ecosystem restoration undertaking shall have adverse effect to historic properties.' In compliance with Section 106 of the NHPA, your concurrence to this determination is respectfully being sought.

Should your office have any questions, please contact Mr. Kanalei Shun, Archaeologist of my Environmental Program Branch, by telephone at (808) 835–4097 or e-mail kanalei.shun@usace.army.mil.

Sincerely,

Anthory J. Paresa, P.E.

Deputy District Engineer for

Programs and Project Management

August 26, 2003

Milton Yoshimoto, Project Manager Department of the Army U.S. Army Engineer District, Honolulu Fort Shafter, HI 96858-5440

Re:

Saipan Lagoon Aquatic Ecosystem Restoration Project

Consultation No. I-PI-03-290

Mr. Yoshimoto:

This responds to your request for a current list of threatened and endangered species located in and around the area of the proposed Saipan Lagoon Aquatic Ecosystem Restoration project located on the island of Saipan, Commonwealth of the Northern Mariana Islands (CNMI). We provide the following comments and information under our statutory authorities under the Endangered Species Act of 1973, as amended, 16 U.S.C. 1531 et seq., and the Marine Mammal Protection Act of 1972, as amended 16 U.S.C. 1361 et seq. (MMPA).

Threatened green turtles (*Chelonia mydas*), endangered leatherback turtles (*Dermochelys coriacea*) and endangered hawksbill turtles (*Eretmochelys imbricata*) occur in the nearshore waters around Saipan. Endangered humpback whales (*Megaptera novaeangliae*) may be found offshore during the winter season. Other endangered marine mammals that have been sighted in the waters off Saipan include the sei whale (*Balaenoptera borealis*) and sperm whale (*Physeter macrocephalus*).

Marine mammals protected under the MMPA (not endangered or threatened under the ESA) that are found in the waters off Saipan include:

Bryde's whale (Balaenoptera edeni)
Cuvier's beaked whale (Ziphius cavirostris)
Pygmy sperm whale (Kogia breviceps)
Melon-headed whale (Peponocephala electra)
Pygmy killer whale (Feresa attenuata)
False killer whale (Pseudorca crassidens)
Killer whale (Orcinus orca)
Short finned pilot whale (Globicephala macrorhynchus)
Spinner dolphins (Stenella longirostris)
Striped dolphin (Stenella coeruleoalba)
Pantropical spotted dolphin (Stenella attenuata)
Common dolphin (Delphinus delphis)
Risso's dolphin (Grampus griseus)

Critical habitat has not been designated or proposed for any listed species under the jurisdiction of National Marine Fisheries Service (NOAA Fisheries) in Saipan. Also, at this time there are no candidate species in the Saipan area.

Information regarding proposed mitigation measures incorporated into the project will be important in determining whether formal or informal consultation is required for this project. Once our office receives more information regarding the proposed action and an assessment of impact of the proposed action on the applicable species, we can initiate section 7 consultation with your agency.

We appreciate your conscientious efforts to comply with Federal requirements. Should you have further questions regarding our comments for the proposed project and/or the section 7 process, please contact Margaret Akamine or David Nichols at (808) 973-2937.

Sincerely,

of Margaret Akamine

18 February 2003

Kanalei Shun CEPOD-ET-ES U.S. Army Corp of Engineers Pacific Ocean Division Building 230 Fort Shafter, Hawaii 96858-5440

Dear Dr. Shun,

This letter is to document the meeting of 5 February 2003 between yourself and Lon Bulgrin, the CNMI Staff Archaeologist, regarding the proposed Saipan Lagoon Remediation Project. Three separate locations were discussed that would be impacted by the project, the Quartermaster Road area, the China House/ I' Liyang area, and the Cock Fighting Ring area.

The Quartermaster Road area was extensively modified by the American military during World War II. A 1951 map depicting immediate post-war conditions on Saipan shows multiple large warehouse building in the area of the proposed earthmoving. It is very likely that concrete foundation pads and other structural elements remain from this logistical complex. Location and documentation of these historical resources will need to occur previous to mechanical clearing or excavation within this area. There is a procedure for requesting demolition of historical structures and structural remnants within the Commonwealth. Measured plan and profile drawings, 5 inch by 7 inch photographs taken from a minimum of two different directions, and a letter of justification are all required in a formal request for the demolition of historical structures. The Historic Preservation Officer then makes a decision whether to concur with the request for demolition or to enter into further negotiations with the client to mitigate the undertaking.

The World War II grading and construction activities make it unlikely that surface or shallow archaeological deposits remain intact. However, deeper cultural deposits may still survive. Therefore, monitoring by a qualified archaeologist of earthmoving to a depth of 120 centimeters (4 feet) below surface will be required. Two archaeological technicians from the CNMI HPO will be available to assist in the monitoring.

The Liyang Site, an Ancient Chamorro archaeological site dating to the Latte Period is located within the China House/I' Liyang area. In addition, an historic cemetery dating from the late 1920s into the 1950s is located in proximity to the project. My experience

with the earlier cemetery in South Garapan is that non-Christian Carolinian burials may extend in a fairly wide radius outside of the cemetery bounds.

A systematic subsurface survey will need to be conducted in order to determine the vertical and horizontal boundaries of the Liyang Site within the project area. I recommend a 10-15 meter interval for the test unit locations but this could vary depending on the archaeological research design. Backhoe test units will need to be excavated to a depth of 1.5 meters or 30 centimeters below the level that water is encountered. The archaeological site, as defined by the subsurface survey, should be avoided (with a suitable buffer zone) during excavation within the area. If excavation within the archaeological site is unavoidable a data recovery plan will need to be composed and implemented by a qualified archaeologist. Two CNMI HPO staff members will be made available to assist the ACOE archaeologist or contractor in this survey.

The proximity of the Liyang Site and the historic Liyang Cemetery indicates a high probability that Ancient Chamorro archaeological deposits and historical burials are located within portions of this project area. However, not all of this extensive land parcel has the same likelihood of cultural remains being present. Therefore, the project area could be stratified based on assigned probability for the presence of historical and archaeological remains. Archaeological monitoring for all earthmoving activities will need to be conducted in areas of high probability. Archaeological monitoring to a depth of 120 centimeters (4 feet) can be conducted for the lower probability areas. Two archaeological technicians from the CNMI HPO staff will assist in the archaeological monitoring.

Human remains discovered in the course of earthmoving will need to be treated in accordance with the Procedures for the Treatment of Human Remains in the Commonwealth of the Northern Mariana Islands. The CNMI HPO will facilitate the excavation and treatment of any human remains discovered.

The Cock Fighting Ring area is a low probability area for historical or archaeological resources. A surface survey to identify any resources within the land parcel should suffice to investigate this portion of the project area, assuming that no significant sites are discovered. Again, two staff members of the CNMI HPO will be available to assist this survey.

Thank you for consulting with our office well in advance of this important project. Early consultation allows problems to be addressed well in advance of the construction phase and serves to limit costly delays. Our office is pleased to assist the Army Corp of Engineers in this project through our trained archaeological staff. If we can be of further assistance or if you have further comments or questions in regards to this project please feel free to contact either myself or Lon Bulgrin.

Sincerely,

Epiphanio E. Cabrera Jr. Historic Preservation Office

November 19, 2003

Milton T. Yoshimoto Project Engineer U.S. Army Corps of Engineers Honolulu District Bldg. 230, Fort Shafter, Hi 96858-5440

Dear Mr. Yoshimoto:

CRMO is providing the additional information you requested in your project update of October 2003 and received by CRMO on November 3, 2003. The items of concern or information needing clarification prior to the completion of the conceptual design of the project restoration alternatives are as follows:

- 1. CRMO conducted a wetland site assessment in both the Quartermaster and the China House sites as specified in the US Department of Defense Figure (Saipan FUD Sites and CRM Areas of Particular Concern, 1999). On November 10, 2003, a wetland investigation was conducted in the Quartermaster and the China House sites. CRMO finds no evidence of wetland in these areas.
- 2. The tradewinds come from the north to northeast. Generally, the air quality around the Quartermaster and the China House sites is good. There are periods of degradation due to traffic in the form of dust and vehicular emissions. Air pollution can be mitigated by the retention of frontage vegetation and by developing dust control measures onsite during construction of the storm water infiltration/retention system.
- 3. The proposed project noise impact can be considered insignificant based on other EIA studies conducted for CRMO major siting permit in adjacent areas. It is understandable that heavy equipment creates noise. However, this work can be restricted to daylight hours and therefore, noise would not be a real concern.

- 4. Traffic congestion will most likely not be a problem. The proposed project should be able to develop its traffic control system to mitigate and avoid traffic congestion during peak hours.
- 5. The CRMO Marine Monitoring Team (MMT) has submitted its detailed biological lagoon analysis on seagrass transect studies. On November 17, 2003, Mr. Peter Houk send an email to Dr. Spengler, Environet, to contact him should he needs further information on the MMT lagoon studies.
- 6. The attached Saipan aerial photo shows land values.

Should you need additional information, please let us know.

Sincerely,

Director

Documented Meetings on Saipan

#### May 18, 2002

## Subject: Summary of Work Tasks Completed during Environet's May 2002 Trip to Saipan

Steve Spengler and Matt Neal of Environet arrived on Saipan on Monday, May 6<sup>th</sup>. Dr. Spengler stayed in Saipan until Wednesday May 15<sup>th</sup> while Mr. Neal stayed on the island until May 12<sup>th</sup>. Dr. Spengler spent a day on Guam on May 15<sup>th</sup>, returning to Honolulu on May 16<sup>th</sup>.

The table below lists the people who were contacted during this visit to discuss various aspects of the Saipan Aquatic Ecosystem Restoration project.

Division of Historic Preservation, SPS #741, Box 10006, Saipan, MP 96950

The major tasks completed during this site visit are summarized below:

- 3/4 Downloaded pressure transducer and rainfall data from monitoring locations at the Hariguchi and Pizza Hut Buildings as well as from beneath the intersection of Quartermaster and Middle roads.
- 3/4 Reviewed aerial and other photograph database available at the University of Northern Marianas Pacific Collection laboratory.
- 3/4 Retrieved AutoCAD images for the shoreline delta areas from Meridian Surveying.
- 3/4 Reviewed As-Build Drawings from the Phase 4 road improvements along Middle Road that were completed in 1992.
- 3/4 Discussed potential restoration alternatives with three employees of the Fish and Wildlife Service and the Department of Fisheries.
- <sup>3</sup>/<sub>4</sub> Installed a pressure transducer in the drainage culvert beneath Middle road across the street from the Subway Sandwich shop.
- <sup>3</sup>/<sub>4</sub> Talked with Jun Beltran of Geotesting about compiling percolation data for the project watershed.
- <sup>3</sup>/<sub>4</sub> Installed a third automated rain guage on top of the Geotesting Building.
- <sup>3</sup>/<sub>4</sub> Collected stormwater samples from Drains Number 6, 11 and 13 between 6 to 6:30 AM. Submitted samples to DEQ laboratory (left with Marvin) for nutrient and microbial analysis at about 8:30 AM.
- <sup>3</sup>/<sub>4</sub> Did a quick reconnaissance tour of four potential future wetlands/retention basin sites present within the project watershed: Fishing Dock area, Drain 7 Area (located south of Wendy's), Quartermaster Road Area, and Gualo Rai wetland area. A fifth potential site exists just to the south of the new emergency medical facility located along Middle road.
- <sup>3</sup>/<sub>4</sub> Collected 21 groundwater samples from along the shoreline at low tide between 13:40 and 15:57. Primary sample locations were located at 0.2-mile intervals in moving south from the Fishing Dock. Secondary locations were located at 0.1-mile and 262-foot intervals in the vicinity of the Drain 7 wetland and the Drain 6 site. Analyzed samples in the field for temperature, conductance and pH. The following nine shallow, near-shore groundwater samples were submitted to DEQ for nitrate analysis: GWI-24, GWI-26, GWI-14, GWI-28, GWI-29, GWI-17, GWI-19, GWI-21 and GWI-23.

## Summary of Work Tasks Completed during Environet's June 2002 Trip to Saipan

Steve Spengler and Anson Murayama of Environet arrived on Saipan on Tuesday, June 25<sup>th</sup>. Dr. Spengler stayed in Saipan until Tuesday July 2nd while Mr. Murayama stayed on the island until June 29<sup>th</sup>. Milton Yoshimoto, Carl Larson and Ronald Pang of the USACE also traveled to Saipan on the same flight to attend project related meetings. A chronological summary of work completed during the visit is given below:

#### Wednesday, June 26th

Environet and Corp personnel met with four people (Henry Hofschneider, Mike Sablan, Jude Dickson and Frank Eliptico) from the Office of Public Lands, Northern Mariana Islands during a meeting which began at 9 AM. The main topic of the conversation, which lasted approximately one hour and a half, was to ascertain whether the office of public lands considers acquisition of land for construction of retention basins to be feasible. According to Deputy Director Hofschneider, acquisition of land will be possible but difficult. Mike Sablan agreed to contact various politicians to see if they would be willing to attend the meeting to be held at the CRM office tomorrow at 10:00. Mike will also work with Jesus Takai, the Director of the Division of Lands Registration and Survey, to determine the ownership of the parcels present within the proposed wetland and retention basin locations.

Environet personnel took Corp personnel to the five proposed retention structures to allow them to view each site

Provided Clarissa Tanaka with a list of the dates of stormwater and groundwater samples that were previously submitted to the DEQ laboratory for analysis.

#### Thursday, June 27th

Gave a Powerpoint presentation at the CRM conference room at 10:00 AM. A total of 14 people attended the meeting (Ronald Pang, Carl Larson, Anson Murayama, Steve Spengler, Keith Aughenbaugh, Arnold Palacios, Frank Eliptico, Jude Dickinson, Milton Yoshimoto, Kerry Pate, Clarissa Bearden, Ray Tebuteb, Haidre Eugenio, and Thorne Abbott). Fielded a few questions from meeting participants. Milton and Steve talked with reporter from the Marianas Variety and Steve was interviewed by correspondent from local television station.

Downloaded rainfall data from the Hariguchi, Pizza Hut and Geotesting Building sites. Discussed getting infiltration data from Geotesting. I will revisit Geotesting personnel tomorrow afternoon. I will also revisit Clarissa Tanaka tomorrow afternoon to obtain all of the analytical data that has been generated by the DEQ laboratory on stormwater and groundwater samples previously submitted to the laboratory. Will also revisit Alfred Pangalinian tomorrow morning to obtain the second round of surveying data and to get

Meridian to shoot the elevations of the drainage culverts located in front of the Subway Sandwich shop and at the intersection of Middle and Quartermaster road.

#### Friday, June 28th

Visited the constructed wetland located at American Memorial Park. Discussed the project with Chuck Sayon, the site manager/park ranger for this park. He photocopied some of the operation and maintenance documents prepared for the project site by Winzler and Kelly. Talked with Brian Bearden about this site. Unfortunately, there is no water quality data available for the project. The wetland currently receives brine generated from the Hyatt's desalinization unit. This leads to a high salinity environment which limits the type of vegetation that can grow in the area to mangrove type vegetation. They are currently trying to grow the indigenous mangrove that is found in adjoining wetland areas. The desalinization process appears to lead to concentrated levels of phosphate and nitrates in the brine generated by the desalinization process.

At 13:00, a meeting was held at the office of the legislature for members of a legislative committee (Department of Land and Natural Resources?). Attendees at the meeting included the following legislators: Arnold Palacios, Pedro Castro, Frank Aldam, Tom Tebutub, Danny Quitugua, and Manuel Tenorio. In addition, the governors assistant, Mr. Bob Schwalbach, attended the meeting. Steve Spengler, Anson Murayama, Milton Yoshimoto, Ron Pang, Carl Larson, and Kerry Pate also attended this meeting. The legislators expressed strong support for the project. The meeting lasted two hours.

Collected percolation test data from the files of Geotesting. Unfortunately, the location of individual percolation tests were not generally available. I recorded the following data from the Geotesting files: calculated percolation rate (inches/hour), lithology encountered in test pit, and location, if available.

#### Monday, July 1st

Held a meeting with Brian Bearden of DEQ to discuss the status of the project. Went through the project powerpoint presentation with Brian. Brian suggested that as part of the beneficial impact analysis that we look at utilizing the Uplands Mitigation Bank, which was signed into legislation in January 2002. This program allows a developer to buy credits for use of land that will impact bird habitat. The Fish and Wildlife Service has identified 97 breeding pairs of Reed Warblers for the purposes of the Upland Mitigation Bank. They have suggested that 2.5 hectacres of land are required per breeding pair, but Throne suggests that an area as little as 1/3 acre per pair might be sufficient. A value of \$55,200 per breeding pair was established in a Memorandum of Understanding document signed between CNMI and the Fish and Wildlife Service. Tina De Cruz (DFW) is the local expert on the reed warbler. Met with Throne Abbott of DFW. He provided some additional information about mitigation banks. They are apparently well established for wetland areas on the mainland, especially California. A possible point of contact for more information would be Steve Morgan of Wetlands, Inc. (916-331-8810). Relevant reference for the reed warbler: Recovery Plan for the Nightingale

Reed-Warbler (Acrocephalus luscinia). Published by Region 1, U.S. Fish and Wildlife Service, Portland, Oregon, April 1998, 62 pp.

Met with Rob Carruth of the USGS to discuss the hydrogeology of the inland part of the project watershed. A hydraulic conductivity value of 1,200 feet/day for the Tagpochau/Mariana Limestone is being used in the on-going USGS modeling efforts. The water levels along Middle road are estimated to be approximately 1 feet above sea level, whereas the water levels measured in the Gualo Rai wells range from 3.5 to 4.0 feet above sea level.

Met with Clarissa Tanaka of DEQ. Clarissa provided me with the analytical data that DEQ has been collecting from near-shore monitoring locations within the project watershed and from periodic near-shore groundwater and stormwater samples collected during previous visits.

Met with Max and Mark of AES to show them where to collect stormwater samples for this study. They will provide water quality monitoring equipment. The first samples will be collected from Drains 4, 6, and 11. Additional samples will be collected from the Hafa Adai and Dai Ichi drainage canals. The samples will be collected from an area below the discharge points where concentrated brine enters both drainage channel.

Downloaded the pressure transducer beneath Quartermaster/Middle Road intersection at 18:00. Reinstalled the transducer at 18:30 and reset the sampling interval to 3 minutes from 1 minute.

Downloaded the pressure transducer beneath road in front of Subway at 18:40. Reinstalled the transducer at 18:45 and reset the sampling interval to 3 minutes from 1 minute.

#### Tuesday, July 2nd

Left the island early this morning.

# **Army Corps presents options** to restore Saipan lagoon

By Haidee V. Eugenio Vanety News Sta"

THE U.S. Anny Corps of Ensineers and its Hawaii-based contractor Environet. Inc. are urging the CNMI government to help in the planned major restoration of Saipan's degrading lagoon.

Yc<tcrday.federal and local officials convened at the Coastal Resources Management to discu-< the five avaolable options to re.tore 1hc "hmd lagoon.

Milton Yo,himoto. project manager of the Amly Corps Honolulu Oi,trict, civil works branch. said the requirements—like providing lunds. easements, right-of-way and necessary relocat ion—need to be enforced her fore lhe acJUal project construction.

··Wilhout locabistance.lhis projec1 may not be realized: said Yoshi111010 during the one-hour mee1ing.

For example, there are five potential sites for the construction of retention/detention basins and wellnnds.

The CNMI government needs 10 ensure thai all lhe privale and public landscovered in the project will be madeavailable along wilh

providing all access roules and relocation of utilities necessary for lhc project construction. its operation and maintenance.

Rep.Amold Palacios.R-Saipan and chairman of the House Comminceon Nutural Resources. said the LegislaiUre and the administration support this project. aut look forward 10 iiS completion.

...We are all one in saying hut we need 10 do something to protect and rc'tore our marine environment: said Palacios. adding thm hbcommiuee may introduce u bill appropriating local fund' for the project.

The options presented by ttle Army Corps and Environct include: no action; collect and convey Mormwaler offshore; con<fluct nelention/detenlinn basins: create con\tructed wetlands: and con, truct combination of relention/detenlion basins and contructed wetlands.

The area under considerulion covers u 1.5-mile length of shoreline in weslern Saipan, from the Garupnn fishing base to the Quarter Masler Road in lersection.

Dr. Steven R. Spengler. senior hydrogeologist of Environet, said a draft CO analysis for each one of the options is expected to be completed in Jan. 2003.

""Thm analysis would include which or the options willgive the be" benefit 10 the environment. and how much would it cost." said Spengler.

In his presentation. Spengler 'aid II he overall project objective i<10 ne'tore degraded ecosySiem 'lructune. function and dynamic proce'-clOalessdegraded.more natuml condition.

.Specilically. an auempt will be made to re-establish. as closely "" po"ible. conditions which would occur in the area in tile absence of hu man changes 10 lhe lan<hcape and hydrology: lle

The analysis will then be presented to the CNMI which will decide "hich of the options to nke.

Representatives from tile Muriana' Public Lands Aulhorily.the Division ofFish and Wildlife and the Division of Environmental Quality were also present during the meeting.

From Mariana's Variety, June 29, 2002

## Summary of Work Tasks Completed during Environet's August 2002 Trip to Saipan

Steve Spengler and Matt Neal of Environet arrived on Saipan on Thursday, August 8<sup>th</sup>. Dr. Spengler and Mr. Neal stayed in Saipan until Saturday August 10<sup>th</sup> at which time they traveled back to Guam for the weekend. They returned to Saipan on the evening of August 11<sup>th</sup>. Ms. Colette Sakoda joined them in Saipan on the evening of August 13<sup>th</sup>. Mr. Spengler, Neal and Ms. Sakoda returned to Honolulu on Friday morning, August 16<sup>th</sup>. A chronological summary of work completed during the visit is given below:

#### Friday, August 9th

Environet personnel installed pressure transducers in monitoring wells located at the Mobil/McDonalds gas station located along Beach Road and the inland Mobil station located along Middle road in Garapan. Survey elevation for the top of casing for both wells used was supplied by Max Simian of AGS. The transducer data will be used to monitor changes in groundwater elevation over a five day period to allow a calculation of overall groundwater gradient for the shallow basal aquifer that underlies the southern portion of Garapan.

At 11:30, we removed the transducer that was in the drainage culvert fronting the Subway sandwich shop along Middle road. We were unsuccessful at downloading the pressure information, since we constantly got an error message as the transducer was completing its download of information. We also apparently overwrote the last months data present on the transducer. We reprogrammed the transducer and installed in the McDonalds well.

Starting at about 2:00 PM, we began sampling 21 near-shore groundwater locations located along the shoreline region of our project area. The samples were collected around the time of low tide. Field measurements were made on the collected groundwater samples as well as samples in Whirlpacks and sample jars to allow us to measure Enterococci, nitrate, phosphate and TDS levels using the colorimetric and turbidity meters supplied by DEQ. A subset of the samples collected was submitted to the DEQ laboratory for microbiological analysis (enterococci).

#### Monday, August 12th

Collected stormwater runoff from an early morning rain event that occurred at about 8:30 AM. Stormwater samples were collected from drains 6, 11 and 14 (Hakubaton Building) as well as from the drainage ditch located in front of the Dai Ichi Hotel.

Stormwater discharge rates were measured at a number of drainage channels during a follow-on rain burst that took place around 9:30 AM. Runoff measurements were also collected from the Quartermaster drainage culvert during the end of this rain event.

Max Simian of AES also sampled this particular storm event. We will submit both sets of stormwater data to Sequoia Analytical for analysis of priority pollutants metals levels (including Barium).

Successfully downloaded the pressure transducer beneath Quartermaster Road. Unfortunately, all of the rain gauges had been inadvertently turned off on June 27<sup>th</sup> and thus no rainfall record is available for the intervening time period. The rain gauges were reactivated around 4:30 PM.

Talked with Peter Houk about the write-up for the historic aerial photograph review and offshore lagoon habitat write-up for the project. Peter will begin working on the write-up this week and will e-mail us the remainder prior to him leaving for Florida.

## Wednesday, August 14th

Held a meeting at 9:00 AM at the offices of CRM. Discussed the land acquisition aspects of the project with members of CRM and the Marianas Public Land Committee? People in attendance included: John Starmer, Vince Castro, Philip Sablan and Benny Pangalinan. Others in attendance include: Steve Spengler, Matt Neal, Colette Sakoda, Milton Yoshimoto and Karl Larson. Discussed any possible land use restrictions for the five tentative locations for retention basins/constructed wetlands. Vince told us that we do not have to consider the Fishing Dock site because of future lease obligations for the site.

Steve and Colette visited Vince Castro to obtain information about land use aspects of the future project. Vince also explained the organization of the CNMI government. Vince informally suggested that a land value of around \$30 a square meter might be more representative for the areas that will be potentially acquired. Steve showed Colette around the island. Photocopied the drainage study that had been previously completed for the Garapan region of Saipan by the Army Corps in 1987.

## Thursday, August 15<sup>th</sup>

Held an information meeting at the chambers of the CNMI legislature to discuss the progress of the project. The legislators had numerous questions about the project. Many

of the questions centered around the funding requirements of the project. The majority of the comments came from the speaker and vice-speaker of the house as well as from representative Atta.

Decided to eliminate the Gualo Rai and Pacific Medical Sites from future consideration. Rather, we will consider evaluating the natural sinkhole site located behind the cock fighting complex which is located Mauka of Middle road.

Steve, Colette and Carl visited the following agencies to obtain additional information about the EIS aspects of the future ecosystem restoration project: DEQ (Brian Beardon), DPW (nobody showed), Division of Historic Preservation (Lon Bulgrin).

## Friday, August 16<sup>th</sup>

Left the island early this morning.

#### Summary of Visit to Saipan from 4/4/04 to 4/7/04.

Flew to Saipan on 4/4/04.

4/5/04: Met with Jack Salas, Steve Tilley, Milton Yoshimoto at the CRM office from 7:30 to 8:30 to discuss the Saipan AER project. It was decided at this meeting to extend the project area to the northern property boundary of the Hafa Adai hotel, so that the Cock Fighting Arena site could be included in the restoration analysis.

Gave a powerpoint presentation to members of the Saipan legislature from 9:15 to 10:45. Attendees at the meeting included Jack Salas, Steve Tilley, Milton Yoshimoto, Uyen Tran, Steve Spengler, Timothy Villagomez, Clyde Norita, Miram Seman, and three other legislators who did not provide business cards. After the powerpoint presentation, there was a lot of talk about the funding aspect of the project and the timing of when funds needed to be committed.

From 11:00 to 11:30, Milton, Steve, Uyen, Jack and Steve Tilley went to the shoreline in front of the Hafa Adai in order to verify the location of the extended northern boundary of the project.

Steve, Uyen Hilary and Kathy visited the cock fighting arena site and the ephemeral stream gulch to view the proposed restoration system for this area.

4/6/04: Met with Brian and returned the copy of his design plan for the wetlands informational trail. Obtained a copy of a prior Corp reconnaissance trip report for Lake Susupe. Obtained a copy of a detailed shape file for Saipan from Ken Cochrain. Got some new publications from the technician (George?) who was present at the USGS office. Talked with Genevieve Cabrera of the Division of Historic Preservation about the previous work that has been conducted in the Lake Susupe area. She said that a detailed study and analysis of cores collected by archaeologists from the middle of Lake Susupe, which will describe the flora and changes that have occurred within the Lake over the past 7000 years, will be submitted by Steve Athens and his archaeological firm within the next month. Genevieve also said that she would e-mail me some files of previous stratigraphic chronology work conducted by other researchers.

Noticed that the proposed China House site had been extensively cleared of vegetation recently. This area is apparently owned by Perry Tenorio who would like to turn the area into a driving range. There is a retention basin present at the site but the temporary weir installed to hold back runoff crossing the property is woefully inadequate.

List of Key Players from the April 2004 Trip

Project: Saipan Aquatic Ecosystem Restoration Study

Project No.: F01-009
Date: July 27, 2004

Subject: July 20<sup>th</sup> Site Visit – Trip Summary

#### **Summary:**

Site Visit – 20 July 2004 James Pennaz, USACE and Ryan Yamauchi, EI

09:00 Met with CRM at CRM Office Conference Room

Attendees: Mr. Jack Salas, CRM; Mr. Benny Pangelinan, CRM; Mr. Michael Tenorio, Equitable Realty

Discussion of Mr. Tenario's property (China House Detention Basin Site):

- Mr. Tenario is currently working with DPW to get a permit for the development of a driving range on the property.
- Mr. Tenario is willing to grant a 10-foot drainage easement along the southern and western boundaries to allow for transport of storm water.
- A small detention basin has been already been constructed in the northwestern corner of the property. Mr. Tenario is willing to allow continued use of this corner as a detention basin and may be able to get two additional adjacent family parcels for use as a detention basin.
- Drainage from the detention basin is the existing natural drainage way.

#### Discussion of Design:

- Mr. Yamauchi discussed complexities with CRM regarding the lack of a master plan for the storm drainage system and potential creation of new flooding areas should the transport system be altered. Mr. Salas suggested that we discuss this with DEQ.
- CRM wants EI to identify which of the parcels are required for the three different areas identified. CRM would like to start the process of property acquisition soon, so that further developments are not planned within the parcels required.

#### 10:00 - 12:00

Escorted by Benny to the China House site. Walked the site to observe the construction on Mr. Tenario's property. Observed that the downstream drainage way was overtopped during the last heavy rainfall event.

Escorted by Benny to the Arena site. Observed that the majority of the excavated quarry area has been filled. Drove the area upgradient from the Arena site.

Observed that a few unpaved roads were washed out/damaged due to last heavy rainfall event. Drainage in this area is overland flow in a number of directions. There are no distinct drainage features.

### 13:30 Met with Brian Bearden, DEQ.

Brian mentioned that DPW was starting on a drainage master plan for the study area, but this may be a few years away from completion.

The drainage standards/manuals will be adopted sometime next year.

The western side of the island will be considered Section 303 impaired, thus requiring establishment of TMDLs.

Brian understands the complexities of not having an existing drainage system and master plan for study area. Brian suggested that we try to design basins that best fit based on the constraints given to us.

#### 14:30

Escorted by Benny to the Quartermaster site. Observed that the grade difference between Middle Road and the underlying parcels would allow for development of a detention basin.

Based on the discussions with CRM and DEQ, Jim and Ryan discussed the options and decided that the design should incorporate the design of the detention basins only, since the intent of this project is to affect water quality in the lagoon rather than flood control. This may be accomplished a number of ways. One suggestion from Jim would be to put a low flow pipe to the detention pond, which would capture the first flush flows with larger flows overflowing to the existing natural drainage ways. This would allow for treatment without causing new and different flooding areas. An evaluation of the portion of treatment expected/achievable for the different storm events (i.e. 1-yr, 2-yr, 10-yr) will be conducted (see attached sketch). Costs and benefits will also be considered.

The lots for each of the sites were generally evaluated to determine the optimum placement of the detention basins. Selected lots were identified during the site visit.

#### Summary of Visit to Saipan from 10/24/11 to 10/28/11.

The project team arrived in Saipan on 10/23/11.

10/24/11: Meeting at the Commonwealth of the Northern Mariana Islands (CNMI) Coastal Resources Management (CRM) office.

#### Attendees:

CNMI CRM: Rose Pangelinan, Ana C. Agulto, Rita Chang, Rachel Zuercher

CNMI Department of Public Works (DPW): Oscar Pangelinan

CNMI Department of Environmental Quality (DEQ): Ryan Okano, Clarissa T. Bearden

National Oceanic and Atmospheric Administration (NOAA): Dana Okano

CNMI Department of Public Lands (DPL): Patricia Seman Rasa

CNMI OMB: Virginia Villagomez

United States Army Corps of Engineers (USACE): Milton Yoshimoto, Kevin Nishimura

Community Planning and Engineering (CPE): Anson Murayama, Frank Camacho

Environet: Sonia Shjegstad, Miya Akiba, Max Solmssen

#### 13:40- meeting began

USACE presented the project history to the group, as well as plans for the project moving forward. The project lost funding prior to the completion of the draft Environmental Assessment (EA)/Environmental Restoration Report (ERR) in 2007. The project has received funding again and has restarted. USACE is anticipated to fund the completion of the EA/ERR, as well as the design of the detention/retention basins. The USACE may be able to fund 65 percent of construction costs, but the CNMI will be responsible for the remainder of construction costs, along with the ongoing operation and maintenance of the detention/retention basins.

Environet gave a power point presentation detailing the project location, history and plans for moving forward.

NOAA asked how the project area was determined since there were runoff issues affecting the lagoon from locations outside the project area.

USACE responded that there were limited public lands available for the project, and that the best available sites were chosen given these land use restraints.

Environet then discussed data needs in preparing the EA/ERR with several members of the attendees, and informal meetings to exchange data later in the week were established.

USACE advised that funding for the construction of the project from USACE is limited, but it may be possible for the CNMI to secure federal funds from outside the USACE to finance their portion of the project costs.

CPE identified the following top three local cooperator responsibilities identified in the presentation as the primary project goals that would help to avoid runoff within the project site conjunction with the construction of the detention/retention basins:

- 1. Pave or armor unpaved roads that contribute majority of sediment to lagoon
- 2. Conduct sanitary sewer surveys and repair damaged portions of sewer system
- 3. Extend sewer lines to replace septic and cesspool systems in watershed

CNMI DPW stated that the implementation of the project should be coordinated with the CNMI Commonwealth Utilities Corporation (CUC).

CRM agreed to coordinate a meeting with CPE, USACE and the CUC on Wednesday, October 26, 2011.

15:00- meeting adjourned.

10/25/2011: Meeting at CNMI Legislator

#### Attendees:

CNMI Legislature: Representative Joseph M. Palacios, Chairman;

Speaker Eliceo D. Cabrera;

Floor Leader George N. Camacho;

Representative Ramon A. Tebuteb, SNILD Chair Representative;

Stanley T. McGinnis Torres, PUTC Chair Representative;

Ramon S. Basa, Ways & Means Chair Representative;

Rafael S. Demapan, JGO Chair;

Representative Fredrick P. Deleon Guerrero, FFA Chair;

Representative Joseph P. Deleon Guerrero, Minority Leader; and

Representative Antonio P. Sablan.

USACE: Milton Yoshimoto, Kevin Nishimura

CNMI CRM: Rachael Zuercher

CPE: Anson Murayama, Frank Camacho

Environet: Sonia Shjegstad, Miya Akiba, Max Solmssen

#### 10:00-Meeting began.

Chairman Palacios welcomed committee members and presenters, and formal introductions were made.

Chairman Palacios called on USACE to conduct the presentation on the Saipan Lagoon Aquatic Ecosystem Restoration Project.

USACE gave a brief project history.

Environet and USACE gave power point presentation detailing project history and planned schedule for current project. USACE outlined the proposed cost sharing for the project budget, and stated that USACE funds are limited to support the design phase of the project, and possibly portions of the construction phase. The CNMI would be responsible for securing funds for a portion of the construction costs, as well as all of the costs associated with ongoing operation and maintenance of the retention/detention basins.

Floor Leader Camacho asked if USACE was planning to address runoff in the Garapan area.

USACE responded that the current project area does not include the Garapan runoff areas. Chairman Palacios voiced concern for investigating possibly contaminated soil areas on Saipan.

USACE responded that the USACE environmental division should be contacted and may be able to help.

11:00: meeting was adjourned.

#### Saipan Lagoon Restoration Project Status Report: October, 2011

10/25/2011: meeting at CNMI DPW

#### Attendees:

CNMI DPW: Martin Sablan, Sonya Dancoe, Tony Camacho

CNMI CRM: Rachael Zuercher

USACE: Milton Yoshimoto, Kevin Nishimura CPE: Anson Murayama, Frank Camacho

Environet: Sonia Shjegstad, Miya Akiba, Max Solmssen

13:30-Meeting began

#### Introductions

USACE delivered brief project background.

Environet and USACE gave power point presentation detailing project history and planned schedule for current project. USACE outlined the proposed cost sharing for the project budget, and stated that USACE funds are limited to support the design phase of the project, and possibly portions of the construction phase. The CNMI would be responsible for securing funds for a portion of the construction costs, as well as all of the costs associated with ongoing operation and maintenance of the retention/detention basins.

CNMI DPW informed USACE of the CNMI Hazard Reduction Project that is planned to include repaving and striping of Beach Road. CNMI DPW stated that identifying lands for the proposed project will be a challenge.

CPE and CNMI DPW agreed to share information and stay in close communication regarding the planning and implementation of both the proposed detention/retention basins, and the CNMI DPW hazard reduction project.

CNMI DPW stated that the operation and maintenance of the detention/retention basins may be a problem due to lack of funding.

CPE stated that they will work to incorporate specifications in the design of the basins to allow for less maintenance. However, the design must also adhere to current CNMI DEQ standards.

CNMI DPW provided CPE with the scope of work for a portion of the Hazard Reduction Project, and stated that there may be opportunities for partial funding of the detention/retention basin project as a capital improvement project.

CNMI DPW and CPE discussed different design options that would work. CNMI DPW suggested detention basin at American Memorial Park as a good example of an acceptable "wet pond" that adheres to CNMI DEQ standards.

14:40-Meeting adjourned.

#### 10/26/2011

9:30-Environet and CNMI CRM met with Marine Biologist Mr. Peter Hauk of the Pacific Marine Resources Institute to obtain data for the project.

10:15- Environet and CNMI CRM met with Michael C. Tenorio from CNMI Division of Fish & Wildlife Fisheries Research Section to gather data.

10:30- Environet and CNMI CRM met with Lee Perlow from CNMI Department of Lands and Natural Resources, Division of Fish and Wildlife to consult regarding the presence of important biological species at the proposed retention/detention basin sites. 11:00-11:30- Environet, CPE and CRM conducted site visits to the Arena Site, China

14:00- Meeting at Legislator

Attendees:

CNMI Governor: Mr. Benigno Repeki Fitial

CNMI CRM: Rachael Zuercher

House Site and Quartermaster Site.

USACE: Milton Yoshimoto, Kevin Nishimura CPE: Anson Murayama, Frank Camacho Environet: Miya Akiba, Max Solmssen

#### 14:30-Meeting began

Introductions

Environet and USACE gave power point presentation detailing project history and planned schedule for current project. USACE outlined the proposed cost sharing for the project budget, and stated that USACE funds are limited to support the design phase of the project, and possibly portions of the construction phase. The CNMI would be responsible for securing funds for a portion of the construction costs, as well as all of the costs associated with ongoing operation and maintenance of the retention/detention basins.

Governor Fitial made inquiries regarding budget, and concerns about sedimentation in the lagoon. He stated that land acquisition of private lands for a public purpose is allowed under CNMI laws.

15:30-Meeting adjourned.

#### 10/27/2011

- 8:30: Environet met with CNMI CRM to obtain additional data needs.
- 9:15: Environet met with Clarissa T. Bearden from CNMI DEQ to obtain water quality data needs. Environet contacted CNMI Historical Preservation Office (HPO) to begin the Section 106 consultation process.

10:00-14:00: Environet conducted site visits to previously identified potentially contaminating activities (PCAs) within the project area, as well as searched for any new PCAs within the project area.

#### 10/28/2011

8:30-11:30: Environet continued search of the project area for existing and new PCAs End of Trip Report.

#### May 18, 2002

## Subject: Summary of Work Tasks Completed during Environet's May 2002 Trip to Saipan

Steve Spengler and Matt Neal of Environet arrived on Saipan on Monday, May 6<sup>th</sup>. Dr. Spengler stayed in Saipan until Wednesday May 15<sup>th</sup> while Mr. Neal stayed on the island until May 12<sup>th</sup>. Dr. Spengler spent a day on Guam on May 15<sup>th</sup>, returning to Honolulu on May 16<sup>th</sup>.

The table below lists the people who were contacted during this visit to discuss various aspects of the Saipan Aquatic Ecosystem Restoration project.

NAME		AGENCY AND TITLE	PHONE	NOTES
Jack	Salas	CRM, Chief Enforcement	670-234 6623	Co-Sponser
Doug	Mauro	CRM	670-234-6623	GIS / CAD

				Mangilao, Guam 96923

Division of Fish & Wildlife, PMB 2761, P.O. Box 10002, Saipan MP 96950
Division of Environmental Quality, P.O. Box 501304, Saipan MP 96950
Northern Mariana Islands Museum, P.O. Box 504570, Saipan MP 96950
Division of Historic Preservation, SPS #741, Box 10006, Saipan, MP 96950

The major tasks completed during this site visit are summarized below:

- Downloaded pressure transducer and rainfall data from monitoring locations at the Hariguchi and Pizza Hut Buildings as well as from beneath the intersection of Quartermaster and Middle roads.
- ➤ Reviewed aerial and other photograph database available at the University of Northern Marianas Pacific Collection laboratory.
- ➤ Retrieved AutoCAD images for the shoreline delta areas from Meridian Surveying.
- Reviewed As-Build Drawings from the Phase 4 road improvements along Middle Road that were completed in 1992.
- ➤ Discussed potential restoration alternatives with three employees of the Fish and Wildlife Service and the Department of Fisheries.
- ➤ Installed a pressure transducer in the drainage culvert beneath Middle road across the street from the Subway Sandwich shop.
- ➤ Talked with Jun Beltran of Geotesting about compiling percolation data for the project watershed.
- Installed a third automated rain guage on top of the Geotesting Building.
- ➤ Collected stormwater samples from Drains Number 6, 11 and 13 between 6 to 6:30 AM. Submitted samples to DEQ laboratory (left with Marvin) for nutrient and microbial analysis at about 8:30 AM.
- ➤ Did a quick reconnaissance tour of four potential future wetlands/retention basin sites present within the project watershed: Fishing Dock area, Drain 7 Area (located south of Wendy's), Quartermaster Road Area, and Gualo Rai wetland area. A fifth potential site exists just to the south of the new emergency medical facility located along Middle road.
- ➤ Collected 21 groundwater samples from along the shoreline at low tide between 13:40 and 15:57. Primary sample locations were located at 0.2-mile intervals in moving south from the Fishing Dock. Secondary locations were located at 0.1-mile and 262-foot intervals in the vicinity of the Drain 7 wetland and the Drain 6 site. Analyzed samples in the field for temperature, conductance and pH. The following nine shallow, near-shore groundwater samples were submitted to DEQ for nitrate analysis: GWI-24, GWI-26, GWI-14, GWI-28, GWI-29, GWI-17, GWI-19, GWI-21 and GWI-23.

## Summary of Work Tasks Completed during Environet's August 2002 Trip to Saipan

Steve Spengler and Matt Neal of Environet arrived on Saipan on Thursday, August 8<sup>th</sup>. Dr. Spengler and Mr. Neal stayed in Saipan until Saturday August 10<sup>th</sup> at which time they traveled back to Guam for the weekend. They returned to Saipan on the evening of August 11<sup>th</sup>. Ms. Colette Sakoda joined them in Saipan on the evening of August 13<sup>th</sup>. Mr. Spengler, Neal and Ms. Sakoda returned to Honolulu on Friday morning, August 16<sup>th</sup>. A chronological summary of work completed during the visit is given below:

#### Friday, August 9th

Environet personnel installed pressure transducers in monitoring wells located at the Mobil/McDonalds gas station located along Beach Road and the inland Mobil station located along Middle road in Garapan. Survey elevation for the top of casing for both wells used was supplied by Max Simian of AGS. The transducer data will be used to monitor changes in groundwater elevation over a five day period to allow a calculation of overall groundwater gradient for the shallow basal aquifer that underlies the southern portion of Garapan.

At 11:30, we removed the transducer that was in the drainage culvert fronting the Subway sandwich shop along Middle road. We were unsuccessful at downloading the pressure information, since we constantly got an error message as the transducer was completing its download of information. We also apparently overwrote the last months data present on the transducer. We reprogrammed the transducer and installed in the McDonalds well.

Starting at about 2:00 PM, we began sampling 21 near-shore groundwater locations located along the shoreline region of our project area. The samples were collected around the time of low tide. Field measurements were made on the collected groundwater samples as well as samples in Whirlpacks and sample jars to allow us to measure Enterococci, nitrate, phosphate and TDS levels using the colorimetric and turbidity meters supplied by DEQ. A subset of the samples collected was submitted to the DEQ laboratory for microbiological analysis (enterococci).

### Monday, August 12th

Collected stormwater runoff from an early morning rain event that occurred at about 8:30 AM. Stormwater samples were collected from drains 6, 11 and 14 (Hakubaton Building) as well as from the drainage ditch located in front of the Dai Ichi Hotel.

Stormwater discharge rates were measured at a number of drainage channels during a follow-on rain burst that took place around 9:30 AM. Runoff measurements were also collected from the Quartermaster drainage culvert during the end of this rain event.

Max Simian of AES also sampled this particular storm event. We will submit both sets of stormwater data to Sequoia Analytical for analysis of priority pollutants metals levels (including Barium).

Successfully downloaded the pressure transducer beneath Quartermaster Road. Unfortunately, all of the rain gauges had been inadvertently turned off on June 27<sup>th</sup> and thus no rainfall record is available for the intervening time period. The rain gauges were reactivated around 4:30 PM.

Talked with Peter Houk about the write-up for the historic aerial photograph review and offshore lagoon habitat write-up for the project. Peter will begin working on the write-up this week and will e-mail us the remainder prior to him leaving for Florida.

## Wednesday, August 14th

Held a meeting at 9:00 AM at the offices of CRM. Discussed the land acquisition aspects of the project with members of CRM and the Marianas Public Land Committee? People in attendance included: John Starmer, Vince Castro, Philip Sablan and Benny Pangalinan. Others in attendance include: Steve Spengler, Matt Neal, Colette Sakoda, Milton Yoshimoto and Karl Larson. Discussed any possible land use restrictions for the five tentative locations for retention basins/constructed wetlands. Vince told us that we do not have to consider the Fishing Dock site because of future lease obligations for the site.

Steve and Colette visited Vince Castro to obtain information about land use aspects of the future project. Vince also explained the organization of the CNMI government. Vince informally suggested that a land value of around \$30 a square meter might be more representative for the areas that will be potentially acquired. Steve showed Colette around the island. Photocopied the drainage study that had been previously completed for the Garapan region of Saipan by the Army Corps in1987.

## Thursday, August 15<sup>th</sup>

Held an information meeting at the chambers of the CNMI legislature to discuss the progress of the project. The legislators had numerous questions about the project. Many

of the questions centered around the funding requirements of the project. The majority of the comments came from the speaker and vice-speaker of the house as well as from representative Atta.

Decided to eliminate the Gualo Rai and Pacific Medical Sites from future consideration. Rather, we will consider evaluating the natural sinkhole site located behind the cock fighting complex which is located Mauka of Middle road.

Steve, Colette and Carl visited the following agencies to obtain additional information about the EIS aspects of the future ecosystem restoration project: DEQ (Brian Beardon), DPW (nobody showed), Division of Historic Preservation (Lon Bulgrin).

### Friday, August 16th

Left the island early this morning.

Peter Houk, Pacific Marine Resource Institute, PMB 1156, P.O. Box 10003, Saipan, MP 96950

#### September Saipan Trip Summary

Arrive Monday September 16, at 9:00 PM.

#### Tuesday, September 17

- 1) Met with Jack Salas to deliver new wetland site landowner figures. CRM will continue pursuing Right of Entry information from the revised list of landowners.
- 2) Met with John Starmer to discuss lagoon sediment sampling strategy.
- 3) Began stormwater collection system inventory.
- 4) Met with Starmer to turn over sampling gear and containers for the lagoon sediment sampling.

#### Wednesday, September 18

1) Completed lagoon sediment sampling, a total of 18 composite samples were collected from six transects ranging from the near-shore enhalus beds to the offshore enhalus beds located beyond the current channel. The purpose of this exercise is to help determine the extent of contamination within sediment in the lagoon. Four sampling transects were located corresponding to the most heavily sedimented stormwater outfalls along Beach Road within the project area. A single transect was located north of the project site, corresponding to the Dai Ichi Hotel drainage outfall, typically one of the most heavily contaminated areas of the lagoon. Finally, a single transect was located south of the project site, corresponding to the San Jose wetland.

#### Thursday, September 19

- 1) Continued storm water system inventory and measurement (measured culverts, catch basins, retention swales, etc).
- 2) Observed and document stormwater drainage channels, ponding areas within the project site.
- 3) Measured stormwater volume at the Quartermaster/Middle Road intersection.
- 4) Removed pressure transducers from both the Quartermaster and Subway sites.

#### Friday, September 20

- 1) Due to heavy rain and flooding, Proceeded to measure and record stormwater flow volumes along both Beach and Middle Roads several times during the duration of the heavy rain.
- 2) Downloaded data from three rainguages (Harahuchi Bldg, Pizza Hut Bldg, and Geotesting Bldg).
- 3) Downloaded data from both the Quartermaster and Subway transducers and returned them to their respective locations.

#### Saturday, September 21

- 1) Conduct reconnaissance and documentation of flood debris from heavy rains that occurred on Friday.
- 2) Conducted reconnaissance and measurements of the Cock Fight potential constructed wetland site.
- 3) Completed final check of the rainguages, returned field gear to DEQ laboratory.

#### Summary of Visit to Saipan from 4/4/04 to 4/7/04.

Flew to Saipan on 4/4/04.

4/5/04: Met with Jack Salas, Steve Tilley, Milton Yoshimoto at the CRM office from 7:30 to 8:30 to discuss the Saipan AER project. It was decided at this meeting to extend the project area to the northern property boundary of the Hafa Adai hotel, so that the Cock Fighting Arena site could be included in the restoration analysis.

Gave a powerpoint presentation to members of the Saipan legislature from 9:15 to 10:45. Attendees at the meeting included Jack Salas, Steve Tilley, Milton Yoshimoto, Uyen Tran, Steve Spengler, Timothy Villagomez, Clyde Norita, Miram Seman, and three other legislators who did not provide business cards. After the powerpoint presentation, there was a lot of talk about the funding aspect of the project and the timing of when funds needed to be committed.

From 11:00 to 11:30, Milton, Steve, Uyen, Jack and Steve Tilley went to the shoreline in front of the Hafa Adai in order to verify the location of the extended northern boundary of the project.

Steve, Uyen Hilary and Kathy visited the cock fighting arena site and the ephemeral stream gulch to view the proposed restoration system for this area.

4/6/04: Met with Brian and returned the copy of his design plan for the wetlands informational trail. Obtained a copy of a prior Corp reconnaissance trip report for Lake Susupe. Obtained a copy of a detailed shape file for Saipan from Ken Cochrain. Got some new publications from the technician (George?) who was present at the USGS office. Talked with Genevieve Cabrera of the Division of Historic Preservation about the previous work that has been conducted in the Lake Susupe area. She said that a detailed study and analysis of cores collected by archaeologists from the middle of Lake Susupe, which will describe the flora and changes that have occurred within the Lake over the past 7000 years, will be submitted by Steve Athens and his archaeological firm within the next month. Genevieve also said that she would e-mail me some files of previous stratigraphic chronology work conducted by other researchers.

Noticed that the proposed China House site had been extensively cleared of vegetation recently. This area is apparently owned by Perry Tenorio who would like to turn the area into a driving range. There is a retention basin present at the site but the temporary weir installed to hold back runoff crossing the property is woefully inadequate.

List of Key Players from the April 2004 Trip

NAME		AGENCY AND TITLE	PHONE	E-MAIL	NOTES

Meetings held on April 6, 2004

Division of Environmental Quality, CNMI, 3rd Floor Morgen Building, San Jose, P.O. Box 501304, Saipan, MP 96950 Division of Historic Preservation, Department of Community and Cultural Affairs, Caller Box 10007, Airport Road, Saipan, MP 96950

Coastal Resources Management, P.O. Box 10007, Second Floor Morgen Bldg., San Jose, Saipan, MP 96950.

#### **Summary:**

Site Visit – 20 July 2004 James Pennaz, USACE and Ryan Yamauchi, EI

09:00 Met with CRM at CRM Office Conference Room Attendees: Mr. Jack Salas, CRM; Mr. Benny Pangelinan, CRM; Mr. Michael Tenorio, Equitable Realty

Discussion of Mr. Tenario's property (China House Detention Basin Site):

- Mr. Tenario is currently working with DPW to get a permit for the development of a driving range on the property.
- Mr. Tenario is willing to grant a 10-foot drainage easement along the southern and western boundaries to allow for transport of storm water.
- A small detention basin has been already been constructed in the northwestern corner of the property. Mr. Tenario is willing to allow continued use of this corner as a detention basin and may be able to get two additional adjacent family parcels for use as a detention basin.
- Drainage from the detention basin is the existing natural drainage way.

#### Discussion of Design:

- Mr. Yamauchi discussed complexities with CRM regarding the lack of a master plan for the storm drainage system and potential creation of new flooding areas should the transport system be altered. Mr. Salas suggested that we discuss this with DEQ.
- CRM wants EI to identify which of the parcels are required for the three different areas identified. CRM would like to start the process of property acquisition soon, so that further developments are not planned within the parcels required.

#### 10:00 - 12:00

Escorted by Benny to the China House site. Walked the site to observe the construction on Mr. Tenario's property. Observed that the downstream drainage way was overtopped during the last heavy rainfall event.

Escorted by Benny to the Arena site. Observed that the majority of the excavated quarry area has been filled. Drove the area upgradient from the Arena site. Observed that a few unpaved roads were washed out/damaged due to last heavy rainfall event. Drainage in this area is overland flow in a number of directions. There are no distinct drainage features.

#### 13:30 Met with Brian Bearden, DEQ.

Brian mentioned that DPW was starting on a drainage master plan for the study area, but this may be a few years away from completion.

The drainage standards/manuals will be adopted sometime next year.

The western side of the island will be considered Section 303 impaired, thus requiring establishment of TMDLs.

Brian understands the complexities of not having an existing drainage system and master plan for study area. Brian suggested that we try to design basins that best fit based on the constraints given to us.

14:30

Escorted by Benny to the Quartermaster site. Observed that the grade difference between Middle Road and the underlying parcels would allow for development of a detention basin.

Based on the discussions with CRM and DEQ, Jim and Ryan discussed the options and decided that the design should incorporate the design of the detention basins only, since the intent of this project is to affect water quality in the lagoon rather than flood control. This may be accomplished a number of ways. One suggestion from Jim would be to put a low flow pipe to the detention pond, which would capture the first flush flows with larger flows overflowing to the existing natural drainage ways. This would allow for treatment without causing new and different flooding areas. An evaluation of the portion of treatment expected/achievable for the different storm events (i.e. 1-yr, 2-yr, 10-yr) will be conducted (see attached sketch). Costs and benefits will also be considered.

The lots for each of the sites were generally evaluated to determine the optimum placement of the detention basins. Selected lots were identified during the site visit (see attached sketch).

#### Summary of Visit to Saipan from 10/24/11 to 10/28/11.

The project team arrived in Saipan on 10/23/11.

10/24/11: Meeting at the Commonwealth of the Northern Mariana Islands (CNMI) Coastal Resources Management (CRM) office.

#### Attendees:

CNMI CRM: Rose Pangelinan, Ana C. Agulto, Rita Chang, Rachel Zuercher

CNMI Department of Public Works (DPW): Oscar Pangelinan

CNMI Department of Environmental Quality (DEQ): Ryan Okano, Clarissa T. Bearden

National Oceanic and Atmospheric Administration (NOAA): Dana Okano

CNMI Department of Public Lands (DPL): Patricia Seman Rasa

CNMI OMB: Virginia Villagomez

United States Army Corps of Engineers (USACE): Milton Yoshimoto, Kevin Nishimura

Community Planning and Engineering (CPE): Anson Murayama, Frank Camacho

Environet: Sonia Shjegstad, Miya Akiba, Max Solmssen

#### 13:40- meeting began

USACE presented the project history to the group, as well as plans for the project moving forward. The project lost funding prior to the completion of the draft Environmental Assessment (EA)/Environmental Restoration Report (ERR) in 2007. The project has received funding again and has restarted. USACE is anticipated to fund the completion of the EA/ERR, as well as the design of the detention/retention basins. The USACE may be able to fund 65 percent of construction costs, but the CNMI will be responsible for the remainder of construction costs, along with the ongoing operation and maintenance of the detention/retention basins.

Environet gave a power point presentation detailing the project location, history and plans for moving forward.

NOAA asked how the project area was determined since there were runoff issues affecting the lagoon from locations outside the project area.

USACE responded that there were limited public lands available for the project, and that the best available sites were chosen given these land use restraints.

Environet then discussed data needs in preparing the EA/ERR with several members of the attendees, and informal meetings to exchange data later in the week were established.

USACE advised that funding for the construction of the project from USACE is limited, but it may be possible for the CNMI to secure federal funds from outside the USACE to finance their portion of the project costs.

CPE identified the following top three local cooperator responsibilities identified in the presentation as the primary project goals that would help to avoid runoff within the project site conjunction with the construction of the detention/retention basins:

- 1. Pave or armor unpaved roads that contribute majority of sediment to lagoon
- 2. Conduct sanitary sewer surveys and repair damaged portions of sewer system
- 3. Extend sewer lines to replace septic and cesspool systems in watershed

CNMI DPW stated that the implementation of the project should be coordinated with the CNMI Commonwealth Utilities Corporation (CUC).

CRM agreed to coordinate a meeting with CPE, USACE and the CUC on Wednesday, October 26, 2011.

15:00- meeting adjourned.

10/25/2011: Meeting at CNMI Legislator

#### Attendees:

CNMI Legislature: Representative Joseph M. Palacios, Chairman;

Speaker Eliceo D. Cabrera;

Floor Leader George N. Camacho;

Representative Ramon A. Tebuteb, SNILD Chair Representative;

Stanley T. McGinnis Torres, PUTC Chair Representative;

Ramon S. Basa, Ways & Means Chair Representative;

Rafael S. Demapan, JGO Chair;

Representative Fredrick P. Deleon Guerrero, FFA Chair;

Representative Joseph P. Deleon Guerrero, Minority Leader; and

Representative Antonio P. Sablan.

USACE: Milton Yoshimoto, Kevin Nishimura

CNMI CRM: Rachael Zuercher

CPE: Anson Murayama, Frank Camacho

Environet: Sonia Shjegstad, Miya Akiba, Max Solmssen

#### 10:00-Meeting began.

Chairman Palacios welcomed committee members and presenters, and formal introductions were made.

Chairman Palacios called on USACE to conduct the presentation on the Saipan Lagoon Aquatic Ecosystem Restoration Project.

USACE gave a brief project history.

Environet and USACE gave power point presentation detailing project history and planned schedule for current project. USACE outlined the proposed cost sharing for the project budget, and stated that USACE funds are limited to support the design phase of the project, and possibly portions of the construction phase. The CNMI would be responsible for securing funds for a portion of the construction costs, as well as all of the costs associated with ongoing operation and maintenance of the retention/detention basins.

Floor Leader Camacho asked if USACE was planning to address runoff in the Garapan area.

USACE responded that the current project area does not include the Garapan runoff areas. Chairman Palacios voiced concern for investigating possibly contaminated soil areas on Saipan.

USACE responded that the USACE environmental division should be contacted and may be able to help.

11:00: meeting was adjourned.

#### Saipan Lagoon Restoration Project Status Report: October, 2011

10/25/2011: meeting at CNMI DPW

#### Attendees:

CNMI DPW: Martin Sablan, Sonya Dancoe, Tony Camacho

CNMI CRM: Rachael Zuercher

USACE: Milton Yoshimoto, Kevin Nishimura CPE: Anson Murayama, Frank Camacho

Environet: Sonia Shjegstad, Miya Akiba, Max Solmssen

13:30-Meeting began

#### Introductions

USACE delivered brief project background.

Environet and USACE gave power point presentation detailing project history and planned schedule for current project. USACE outlined the proposed cost sharing for the project budget, and stated that USACE funds are limited to support the design phase of the project, and possibly portions of the construction phase. The CNMI would be responsible for securing funds for a portion of the construction costs, as well as all of the costs associated with ongoing operation and maintenance of the retention/detention basins.

CNMI DPW informed USACE of the CNMI Hazard Reduction Project that is planned to include repaving and striping of Beach Road. CNMI DPW stated that identifying lands for the proposed project will be a challenge.

CPE and CNMI DPW agreed to share information and stay in close communication regarding the planning and implementation of both the proposed detention/retention basins, and the CNMI DPW hazard reduction project.

CNMI DPW stated that the operation and maintenance of the detention/retention basins may be a problem due to lack of funding.

CPE stated that they will work to incorporate specifications in the design of the basins to allow for less maintenance. However, the design must also adhere to current CNMI DEQ standards.

CNMI DPW provided CPE with the scope of work for a portion of the Hazard Reduction Project, and stated that there may be opportunities for partial funding of the detention/retention basin project as a capital improvement project.

CNMI DPW and CPE discussed different design options that would work. CNMI DPW suggested detention basin at American Memorial Park as a good example of an acceptable "wet pond" that adheres to CNMI DEQ standards.

14:40-Meeting adjourned.

#### 10/26/2011

9:30-Environet and CNMI CRM met with Marine Biologist Mr. Peter Hauk of the Pacific Marine Resources Institute to obtain data for the project.

10:15- Environet and CNMI CRM met with Michael C. Tenorio from CNMI Division of Fish & Wildlife Fisheries Research Section to gather data.

10:30- Environet and CNMI CRM met with Lee Perlow from CNMI Department of Lands and Natural Resources, Division of Fish and Wildlife to consult regarding the presence of important biological species at the proposed retention/detention basin sites.

11:00-11:30- Environet, CPE and CRM conducted site visits to the Arena Site, China House Site and Quartermaster Site.

14:00- Meeting at Legislator

Attendees:

CNMI Governor: Mr. Benigno Repeki Fitial

CNMI CRM: Rachael Zuercher

USACE: Milton Yoshimoto, Kevin Nishimura CPE: Anson Murayama, Frank Camacho Environet: Miya Akiba, Max Solmssen

#### 14:30-Meeting began

Introductions

Environet and USACE gave power point presentation detailing project history and planned schedule for current project. USACE outlined the proposed cost sharing for the project budget, and stated that USACE funds are limited to support the design phase of the project, and possibly portions of the construction phase. The CNMI would be responsible for securing funds for a portion of the construction costs, as well as all of the costs associated with ongoing operation and maintenance of the retention/detention basins.

Governor Fitial made inquiries regarding budget, and concerns about sedimentation in the lagoon. He stated that land acquisition of private lands for a public purpose is allowed under CNMI laws.

15:30-Meeting adjourned.

#### 10/27/2011

- 8:30: Environet met with CNMI CRM to obtain additional data needs.
- 9:15: Environet met with Clarissa T. Bearden from CNMI DEQ to obtain water quality data needs. Environet contacted CNMI Historical Preservation Office (HPO) to begin the Section 106 consultation process.

10:00-14:00: Environet conducted site visits to previously identified potentially contaminating activities (PCAs) within the project area, as well as searched for any new PCAs within the project area.

#### 10/28/2011

8:30-11:30: Environet continued search of the project area for existing and new PCAs End of Trip Report.

Appendix B
Phase I Report, Saipan Lagoon Aquatic Ecosystem Restoration Study

## FINAL

# PHASE 1 SAIPAN LAGOON AQUATIC ECOSYSTEM RESTORATION PROJECT

# **EXECUTIVE SUMMARY**

A Phase I Aquatic Ecosystem Restoration (AER) Study was prepared for a 1.5-mile length of shoreline located in western Saipan, Commonwealth of Northern Marianas Islands (CNMI). The project site extends from Quartermaster Road to the Fishing Base and encompasses the entire inland watershed that contributes groundwater and surface water runoff to this 1.5-mile length of shoreline as well as the adjacent offshore lagoon area out to the fringing coral reef.

This report provides preliminary restoration alternatives as well as suggestions for additional studies required to establish baseline environmental conditions within the study area. The restoration alternatives discussed include regulatory approaches, improved watershed management, and undertaking infrastructure improvements to reduce the amount of sediments and contaminants that discharge into the ocean.

The baseline data that would be collected in the studies recommended in this report would be used to monitor the progress of future environmental restoration efforts conducted in the area. It is believed that implementation of the recommended remedial measures will lead to an increase in nearshore fish population (as a result of habitat improvement) and a reduction in the frequency of closures of beach recreational areas due to microbiological contamination.

A December 2000 draft Phase 1 AER report was reviewed by representatives from the U.S. Army Corps of Engineers, and employees of the CNMI Departments of Public Works, Coastal Resources Management and Environmental Quality. A total of ten studies were initially recommended in the draft report. The decision was made at a meeting held in Saipan in early March 2001 to focus on the following seven studies during the Phase II portion of this study:

- 1) Stormwater Quality Investigation
- 2) Analyze Lagoon Sediments for Physical and Chemical Parameters
- 3) Marine Habitat Mapping from Historical and Current Aerial Photographs
- 4) Inshore Lagoon Area Seagrass and Associated Fauna Survey
- 5) Inventory of Potentially Contaminating Activities in Watershed
- 6) Hydrologic Study of Runoff Processes in Watershed
- 7) Lagoon Water Quality Investigation

The CNMI Department of Environmental Quality has agreed to assist the U.S. Army Corps of Engineers and their contractors with the offshore monitoring and sample collection portions of these studies.

This report presents the results of the Phase I portion of the Section 206 Aquatic Ecosystem Restoration Study for a 1.5-mile length of shoreline in western Saipan, Commonwealth of Northern Marianas Islands (CNMI) (Figure 1). The overall project objective is to develop restoration actions that would provide a cost-effective means of restoring the degraded nearshore lagoon environment in this area.

The study described in this report was performed for the U.S. Army Corps of Engineers, Honolulu Engineer District (USACE-HED). The project was conducted by Environet Incorporated (EI) under U.S. Army Corps of Engineers contract number DACA83-00-D-0037, Delivery Order No. 0002. Oceanit Incorporated (OI) was subcontracted by EI to conduct a preliminary assessment of the offshore environment within the project area.

#### 1.1 GOALS AND OBJECTIVES OF THE PHASE 1 RESTORATION STUDY

The purpose of this Phase 1 portion of the Aquatic Ecosystem Restoration Study is to: 1) review existing data and identify gaps in the existing scientific data that need to be addressed to establish baseline conditions in the nearshore lagoon environment; and 2) identify potential restoration alternatives for a 1.5-mile stretch of shoreline located between Quartermaster Road and the Fishing Base on the west side of Saipan.

The restoration of tropical marine habitats requires several components to be successful including:

- The natural state of the habitat needs to be known and described;
- Key indicator species that can be monitored during proposed remedial activities need to be identified;
- The proposed remedial method must be cost effective; and
- The effectiveness of the remedial method must be measurable in terms of how well the affected habitat converges in form or function with natural intact habitat.

The scope of work followed the work items described in a cost proposal letter dated September 26, 2000 from EI to Mr. Kent Tamai, the Contracting Officer for the USACE-HED. The following tasks were conducted during this study:

- A reconnaissance survey of the project site was conducted during a week-long field visit to Saipan. Interviews were conducted with local residents and regulatory personnel who possessed pertinent information for the lagoon and contributory watershed.
- Provided a general description of the project area (Section 2.0).
- Reviewed water quality and environmental data available for the Saipan lagoon and the watershed that contribute groundwater, storm water runoff, and sediment to the project shoreline (Section 3.0).

- Evaluated the existing scientific information available for the lagoon and identified gaps in the existing scientific database (Section 3.6).
- Recommended additional studies required to obtain the missing data identified during the literature search and interviews with knowledgeable individuals (Section 4.0).
- Identified Preliminary Potential Restoration Alternatives for mitigating the current environmental degradation occurring within the Saipan lagoon (Section 5.0).

#### 1.2 KNOWLEDGEABLE PEOPLE INTERVIEWED

A number of people who work for various Federal and Local government agencies were interviewed between October 23 and October 28, 2000 in Saipan. Table 1 contains the names and phone numbers of the people contacted during the site visit to Saipan. The concerns expressed by the individuals interviewed are summarized in Section 1.3.

#### 1.3 LOCAL ENVIRONMENTAL CONCERNS

There is great concern over any threat to the natural ecology of the reef lagoon system because a large percentage of Saipan's economy is based upon foreign tourist who are attracted to the island by the spectacular reefs and marine life surrounding the island. Local fishermen who depend upon the reef for subsistence as well as recreational and commercial fishing interests are similarly concerned about the perceived degradation to the nearshore reef system. The following concerns were expressed about the health of the lagoon environment by individuals during the field reconnaissance:

- Sea grass beds are deteriorated in the vicinity of stormwater outlets to the lagoon.
- The nearshore environment is perceived to support a greater abundance of fast growing algae species (Enteromorpha and Hypnea) than previously noted, and this could point to increased nutrient influx into the lagoon.
- The previously white sand beach along Garapan is now tinged with the browns and grays of terrestrial sediments.
- Once plentiful lagoon fisheries are now perceived to be a dwindling resource.
- Lagoon waters that used to be clear in all but the heaviest rainfalls, are now typically discolored brown after every rainfall.
- Sediments from upslope erosion are forming deltas of brown sediments into the lagoon.
- Deterioration in the function of the sea grass beds could allow pollutants to reach and impact the outer coral reef ecosystem.

#### 1.4 REGULATORY FRAMEWORK

Section 206 of the Water Resources Development Act (WRDA) of 1996 provides authority for the United States Army Corps of Engineers (USACE) to undertake restoration projects in aquatic ecosystems such as rivers, lakes, and wetlands. The USACE evaluates projects that benefit the environment by restoring, improving, or protecting aquatic habitat for plants, fish and wildlife. The USACE initially conducts a preliminary study to determine if there is a Federal interest in assisting in resolving the problem. A feasibility study is then conducted to define the problem, identify potential solutions, analyze the costs, benefits, and environmental impacts of the alternatives and select a plan. This project is being conducted under the auspices of this program.

The CNMI has promulgated a number of regulations over the past 15 years to protect the environment. The basic environmental rights can be found in the CNMI constitution that states in Article I, Section 9, that each person has the right to a clean and healthful public environment. The Division of Environmental Quality (DEQ) was formed "to develop and administer programs, including, where appropriate, a system of standards, permits, or prohibitions, to prevent or regulate activities concerning the discharge of pollutants to the air, land, water, wetlands, and submerged lands." DEQ has regulations governing earthmoving activities. The purpose of the earthmoving permits is to prevent soil erosion and to minimize pollution of marine, surface or groundwater resources. Although the National Pollutant Discharge Elimination System (NPDES) program has not been delegated to the CNMI, DEQ issues Section 401 Water Quality Certifications to any project that may affect water quality. Section 401 Water Quality Certifications are issued for all projects involving discharges, dredging, or any activity in wetlands. This CNMI permitting process is closely linked to the USACE Section 404 permitting program.

The Clean Water Act (CWA) requires that individual States designate water quality limited segments within their jurisdiction and address water quality concerns within these areas in part through the implementation of Total Maximum Daily Load (TMDL) studies. These TMDL studies attempt to quantify the individual components that contribute suspended and dissolved phase constituents to the nearshore environment. The TMDL studies are a required component of future upgrades to Water Quality Management Plans developed for regulated waters within individual States.

DEQ (1999) has recently completed a Section 305(b) Water Quality Assessment Report for the Commonwealth of the Northern Mariana Islands. This report was written following guidance detailed in Section 305(b) of the CWA and allowed determination of the following issues: (1) whether U.S. waters meet water quality standards, (2) the progress made in maintaining and restoring water quality, and (3) the extent of remaining problems in the CNMI. Onshore, the Safe Drinking Water program began implementing the VOC monitoring requirement, as outlined in the CNMI Drinking Water Regulations in January 2000. Public water systems within the CNMI will be required to do VOC testing in order come into compliance with these regulations. DEQ plans on updating the CNMI's Water Quality Standards at the end of the year 2000.

The Coastal Resources Management (CRM) Program was developed to manage all activities within areas designated as Areas of Particular Concern (APC), including the shoreline to 150 feet inland, lagoon and reefs, wetlands and industrial areas surrounding seaports. The Coastal Resources Management Act is outlined in CNMI Public Law 3-47. This act was established to coordinate island development management and specifies policies and rules that regulate activities that have the potential to affect the island's resources. These resources were broadly defined and included marine water and resources, groundwater, wetlands, watersheds and certain designated APC's. Prior to the initiation of any large development in the CNMI, the developer must obtain a CRM major siting permit. The CRM permitting process provides all of the appropriate government agencies an opportunity to inform the developer the various permitting requirements and general areas of concern for the proposed project. CRM also has an active monitoring and enforcement section.

Soil and Water Conservation Districts were created on Saipan by Public Law 4-44 which outlines methods for conserving, developing and using the soil and water resources on the island to control and to prevent erosion and flooding and to improve agricultural water management.

The CNMI has designated two classes of water (AA and A) for marine uses. The CNMI Water Quality Standards define these classes of water as follows: "The CNMI has designated two classes of marine waters: A and AA. Class AA represents high-quality waters that are considered to be in a "natural" and "pristine" state. The CNMI Water Quality Standards states that "to the extent practicable, the wilderness character of such areas shall be protected," and does not permit any discharge of pollutants in class AA waters. Class A waters have been designated in two parts of Saipan, and generally represent a slightly lower quality of water in which some discharges may be permitted, for example, the two sewage treatment plant outfalls on Saipan. Nevertheless, Class A waters must support recreational use and the propagation of fish, shellfish, and wildlife, and strict water quality standards have been set for the protection of these uses in Class A marine waters. Additionally, further protection is afforded through the CNMI Anti-Degradation Policy, which is part of the Water Quality Standards and protects existing uses and water quality in any waters, despite their classification."

Almost all of the coastal marine waters on Saipan are designated as Class AA, including the project site. These waters should remain in their natural pristine state as nearly as possible with an absolute minimum of pollution or alteration of water quality from any human-related source or actions. The uses protected in these waters are the support and propagation of shellfish and other marine life, as well as the conservation of coral reefs and wilderness areas, oceanographic research, and aesthetic enjoyment and compatible recreation inclusive of whole body contact (e.g. swimming and snorkeling) and related activities. The lagoon area within the project site is designated as Class AA waters.

## 2.1 SITE LOCATION

The project site extends from Quartermaster Road to the Fishing Base along the western shoreline of the island of Saipan, CNMI (Figure 1). The project area encompasses the entire inland watershed that contributes groundwater and surface water runoff to this 1.5-mile length of shoreline as well as the adjacent offshore lagoon area out to the fringing coral reef. The general coordinates of the project site extend from 15° 11' to 15° 12' north latitude and 145° 42' 31" to 145° 42' 32" east longitude.

#### 2.2 SITE DESCRIPTION

The shoreline in the project area consists of a narrow sand beach. The beach consists mainly of loose limesand with some gravel, shell, and coral rubble, over calcareous gravel and beach rock. These sediments are primarily medium-to course-grained and well sorted. The beach is topped at the high water mark by a strip of grasses, vines, and trees, followed by a concrete pedestrian path further inland. The 2.8-mile long concrete pedestrian walking path that meanders between the narrow sandy shoreline and Beach Road. Picnic facilities, numerous trees, vehicle turnout areas, a memorial to fishermen lost at sea (13 Fishermen Monument), a Japanese tank monument, and concrete defensive bunkers built by the Japanese during the war are also found along this section of shoreline. The northern boundary of the site contains an earthen pier that was built during the Japanese period on the island. A dilapidated barge that was formerly used as a restaurant rests firmly aground just to the south of this earthen pier. The southern boundary of the site is opposite Quartermaster Road. The area to the east of Beach Road contains numerous businesses built on private land, including restaurants, hardware and stationary stores, a car lot and several strip malls.

Beach Road is a two lane undivided, signaled asphalt highway that was improved by the US Military following WWII, but not completely paved along its length until about 1985. Middle Road runs parallel to and about half-mile inland of Beach Road, and was improved to a paved, four-lane undivided and signaled asphalt highway in about 1990. Two paved roads link these two highways, Island Power Road to the North and Quartermaster Road at the Southern boundary of the project area. A number of coral gravel surface roads leading to small commercial and residential buildings are present within the project area. The slope of the land becomes steeper above Middle road and the watershed is broken into a series of irregular hills and valleys containing intermittent streams.

The coastal areas are vegetated with ironwood (Casuarina equisetifolia), sea hibiscus (Hibiscus tiliaceus) and a number of ornamental trees with an understory dominated by grasses and seaside morning glory (Ipomoea pescaprae). The inland portions of the project site are either paved or overgrown by scrub vegetation dominated by tangantangan (Leucaena leucocephala), ivy gourd (Coccinia grandis), and occasional ironwood and coconut trees.

#### 2.2.1 Climate

The climate in Saipan is warm and humid throughout the year and is classified as tropical marine, with an average temperature of between 75 to 80 degrees Fahrenheit (Van der Brug, 1985). Rainfall in the study area is seasonal and averages about 75 to 80 inches/year. The wet season usually extends from July through November, followed by a dry season from December through June. Saipan experienced drought-like conditions during 1998, when the rainfall between January and November totaled roughly 41 inches, or roughly half the annual mean.

The dominant winds in the Northern Marianas are tradewinds, which blow from the east or northeast. These winds are strongest and most constant during the dry season, when wind speeds of 15 to 25 miles per hour are common. During the rainy season, the tradewinds often cease, and on some days the weather may be dominated by westerly moving storm systems that bring heavy showers or steady, at times torrential, rains. These episodic, heavy rainfall events contribute the majority of the sediment and surface water runoff that reaches the nearshore lagoon environment. Some of these heavy rainfall events occur during typhoons.

#### 2.2.2 Physiography and Soil

The project site is situated in the western central part of the island of Saipan. The site potentially receives runoff and sediments from the southern half of the West Takpochao watershed, which extends roughly 2 miles inland to the limestone ridge that peaks at 1,540 feet above mean sea level on the summit of Mount Takpochao. The area between the shoreline and Middle road is a slightly to moderately sloping coastal plain composed of unconsolidated limestone derived sediments. The area inland of Middle road possesses the characteristic geomorphology on the island of Saipan with slightly to moderately sloping topographic plateaus separated by seaward-facing scarps of emergent limestone.

The characteristics of the surface soils generally vary in moving inland from the shoreline to upland areas of the watershed (Figure 2). The lowland areas that extend from the shoreline to just inland of Middle road are dominated by soils of the Chinen-Urban Land Map Unit (Young, 1989). These soils are highly porous and account for the lack of natural streambeds or continuous drainage ways across the lowland areas. During the Japanese and German occupations of these islands, much of these lands were in intensive agricultural use. The areas upland of Middle Road in the vicinity of Gualo Rai are covered by soils of the Kagman-Saipan Map Unit while further inland the land area is dominated by the Takpochao-Chinen-Rock Outcrop Map Unit. The Chinen-Urban Land Map unit in the lowlands between Middle road and the Beach Road is the most soil unit most prone to erosion in the area. However, the largest percentage of the sedimentation that occurs along the Beach road drainages appears to come from quarried limestone backfill used for road and lot surfacing, rather than from erosion of the underlying native and disturbed soils.

#### 2.2.3 Soil Erosion

Sediment transport to lowland areas occurs naturally in all island systems. In the project area, the amount of sediments being transported to the lagoon environment has increased in conjunction with the spreading urbanization of the lowland areas within the watershed. The increased number of roofs, roads, and other paved areas impervious to rain increases the amount of runoff and tends to channel the runoff between properties. Construction activities and clearing of the natural vegetation tend to disturb the natural soils rendering them more susceptible to sheet and rill erosion. A decline in coverage by natural vegetation due to increased urbanization also limits the ability of the substrate to hold rainfall and makes these remaining lands more subject to runoff and erosion. The resulting increased levels of runoff and sedimentation to the lagoon overloads the ability of the natural seagrass community to cope with these pollutants and can damage coral reefs and associated ecosystems. Damage to coral reef ecosystems can result from direct sedimentation onto coral polyps or from increased nutrient concentrations that may lead to overgrowth by algae species. A shift in reef species towards more nutrient tolerant and less diverse communities will also lead to changes in the fish populations inhabiting the reef. In addition, less diverse communities of coral are more susceptible to damage during natural disasters such as typhoons. The most serious consequence however, is that any perceived decrease in the quality of the coral reef ecosystem is likely to have a negative impact on tourism on Saipan.

The Soil Conservation Service estimated erosion rates for Saipan soils present in the Kagman Watershed on the eastern side of the island. The average erosion rate from the forested upper watershed is estimated to be about three tons per acre per year while areas under construction may exceed rates of 20 tons per acre per year. The developed homestead area in Kagman, which is situated on a relatively flat limestone plateau, yields between two to five tons of soil per acre per year. Erosion rates for the soils present within the project watershed are not available. However, initial observations made during the reconnaissance field visit of eroded gravel roads, obvious sedimentation in storm drain gullies, and occasional lapses in implementation of Best Management Practice (BMP) regulations at construction sites suggest that erosion rates may be high.

# 2.2.4 Regional Geology and Hydrogeology

The island of Saipan is composed of a volcanic core upon which a series of discrete limestone formations have been deposited by coral reefs when these sections of the island were below sea level. Roughly, 90 percent of the surface of the island is currently mantled with limestone, with the remaining areas chiefly comprised of volcanic outcrops and unconsolidated beach or marsh deposits (Figure 3). The aerial distribution of rock type on the island has been created by successive episodes of tectonic uplift resulting from the flexure of the outer edge of the Philippine Plate in response to subduction of the Pacific Plate to the east of Saipan along the Marianas trench (Karig, 1971). The thick fringing limestone units, which are exposed at elevations of up to 1,540 feet above mean sea

level on the summit of Mount Tagpocahu, have become sub-aerially exposed as a result of these tectonic processes.

The western half of the island, where the site investigation was conducted, is bordered by a large barrier reef and lagoon. Cloud et al. (1956) show the Garapan coastal plain to be underlain by recently emerged lime sands that overlie competent limestone reef at varying depths. Groundwater in the western coastal portions of Saipan occurs as an unconfined brackish water lens that overlies saltwater. The regional aquifer at the subject site is made up of the coral and coral-derived material of the Marianas Formation and the overlying lime sands. Due to the relatively high permeability of these units, the water levels within this aquifer fluctuate with ocean tides. Historically, limited amounts of generally brackish water have been exploited by wells dug along the coastal plain into this unit. Water quality measurements made on a number of wells located within the project watershed are compiled in Table 2. This data shows that the majority of the wells produce very brackish water with somewhat elevated concentrations of nitrate.

#### 2.2.5 Watershed Delineation

The Coastal Resources Management Commission has delineated eleven major watersheds on the island of Saipan. The project site is located within the West Takpochao watershed (Figure 4). This watershed extends along the shoreline from about 500 feet south of Quartermaster Road to the area just north of Charlie Dock at Tanapag Harbor. The watershed extends inland to the ridgeline that runs up to Mount Takpochao and continues on through the Capitol Hill area.

#### 2.2.6 Coral Reef and Lagoon Habitat

Amesbury et al (1979) described 24 habitats in Saipan Lagoon of which eleven are present fronting the project site. These habitat types are expressed and expanded upon in the Saipan Lagoon Use Management Plan (Duenas and Swavely, 1995). This document divides the lagoon into several planning areas of which Planning Area 5 ("from the small cove opposite the fisheries complex in Garapan south to San Jose Beach") encompasses the project area. Habitats in the project are delineated in Figure 5 and include the following:

- Inshore Seagrass Beds and Patches
  - o Habitat 2. Seagrass (Enhalus) in sand, to 0.3m deep
  - o Habitat 3. Seagrass (Halodule) in sand, to 0.6 m deep
- Mid-Lagoon Sandy Areas
  - o Habitat 4. Seagrass (Halodule) and algae in sand and dead coral, to 1 m deep
  - o Habitat 5. Sand, coral rubble and small live corals with algae (Dictyota, Goodlea, Homothanmion), to 1 m deep
  - o Habitat 6. Sand with "Sargassum", to 1 m deep

- o Habitat 7. Sand and coral rubble with Laurencia, to 1.6 m deep
- o Habitat 11. Sand and blue-green algae, to 7 m deep
- o Habitat 14. Dead coral patches in sand with Halimeda and Dictyota, to 2 m deep
- o Habitat 15. Sand with live beds of staghorn corals, to 3 m deep

#### • Lagoon Barrier Reef Flat

- o Habitat 21. Submerged barrier reef with large live coral
- o Habitat 22. Submerged barrier reef with large live coral and algae (Bryopsis, Halimeda, Avrainvillea) to 4 m deep

The focus of this project is the inshore habitat since it receives the majority of the fresh water pollution and serves as the first line of defense for the valuable coral reef and fisheries resources further offshore. This area is described in greater detail below.

The inshore zone is generally comprised of a sand and sand/silt/rubble substrate covered by thick stands of seagrass and algae with only an occasional coral head or limestone outcropping. Because of the heavy input of fresh water (runoff and groundwater) into this environment, dense beds of the large bladed tall (up to 3 feet) seagrass Enhalus acoroides are found in a 10 to 50 meter wide band along the shoreline. Freshwater and entrained nutrients are known to enhance the growth of this sea grass but would have a negative impact on any corals in the area. Intermixed between stands of the Enhalus and extended further out into the lagoon, often to the reef, is the very common short sea grass Halodule uninervis which may cover 20 to 70% of the benthic substrate in the lagoon outside the Enhalus beds and inside the coral reef. Algae species are abundant (more so nearshore) including Halameda, Padina, Calurpa spp., Laurencia spp., Acanthophora and Dictyota as the most common Of concern, however, are the noted presence of two types of algae, Enteromorpha, and Cladophora with rapid growth potential that could bloom and become nuisance algae if nutrient levels become significantly elevated. The green, hair-like Enteromorpha was noted along the beach in several areas in the upper tidal area and appeared coincident with areas of fresh water infiltration. The pale hair-like algae Cladophora was noted in the inner lagoon area adjacent to the northern edge of the project area.

Corals in the inshore zone are very sparse and are characterized by scattered, small colonies of *Porites lutea* and *Pocillopora damicornis*. Live coral cover is less than one percent overall, but some areas may support colonies of Porites and Pocillopora at densities up to 5%. Invertebrates conspicuous in the inshore zone include the common sea cucumber genuses *Holothuria*, *Actinopyga*, and *Bohadschia*, the large starfish Linckia *laevigata*, and the clam known locally as "Amsum". Inshore fish resources include rabbitfish (Siganus), mullet (Mugilidae), goatfish (Mullidae), snappers (Lutjanidae), the emperor fish (Lethrinus harak), and silversides (Atherinidae). Juveniles of many species may be found in the sea grass beds and occasional predatory species such as groupers, jacks and barricuda may also be present. This resource is utilized by local fishermen for subsistence and sport. Fish are collected with small eye throw-nets, scoop nets, surround-nets, and spears.

Fishermen interviewed expressed the opinion that inshore fisheries resources were in decline, and information from the Division of Fish and Wildlife (DNR, 1998) would seem to support this contention (Figure 6).

#### 2.3 SITE HISTORY

The Mariana Islands were discovered in 1521 by Ferdinand Magellan and were claimed for Spain in 1565 by de Legaspi. By 1568, the Spaniards relocated all Chamorros living on the Northern Mariana Islands (including Saipan) to villages on Guam in order to suppress indigenous resistance to foreign rule. Carolinians from the outer islands of the Truk district were the first Micronesians to repopulate Saipan in 1815 as a result of being displaced from their home islands by a devastating typhoon. In 1899, Spain sold the Mariana Islands to the Germans who developed coconut plantations for copra production using local labor. In 1914, the Mariana Islands were seized by a Japanese naval fleet during the opening days of World War I. The League of Nations placed the islands under Japanese mandate in 1920. The Japanese actively colonized and cultivated the Mariana Islands during their tenure. For instance, roughly 32 percent of the land area on Saipan was planted with sugarcane by the 1930s. By 1937, a total of 42,000 Japanese were living on the Northern Mariana Islands. A narrow-gauge railway was built around much of Saipan in order to transport harvested sugarcane to the cane mill located in Chalan Kanoa. Garapan and the northern half of the project area served as the commercial center on the island during the Japanese tenure. The island was heavily fortified by the Japanese during World War II as a result of the island's strategic location in relation to the Japanese mainland.

During World War II, United States forces invaded Saipan on June 15, 1944, and successfully captured the island on July 9, 1944. The shoreline at the project site was heavily shelled during the invasion and numerous live and dud ordnance were encountered during construction of the beachpath. The military quickly embarked on numerous construction projects throughout Saipan that required improving the existing transportation system on the island. Beach road and the Garapan area infrastructure was upgraded by the Navy shortly after the war.

Saipan underwent tremendous growth in the 1980s with the growth of the island's tourist and garment industries. This is reflected in the tremendous growth in the islands population from roughly 15,000 in 1980 to over 72,000 in the year 2000.

#### 2.4 LAND USE IN AREA

The two major thoroughfares on Saipan, Beach and Middle Roads, run through the project area. The majority of urban development in the area is concentrated along these two roads. The community of Gualo Rai extends inland of Middle Road. The remainder of the watershed area inland of Middle Road is predominately covered by forest vegetation. The area between Beach and Middle roads

within the study area is currently only heavily developed in the immediate areas adjacent to these two roads. However, it is likely that the entire land area between these two roads will become heavily urbanized within the next decade due to this areas proximity to the island's commercial and governmental centers and the demands of a rapidly increasing population.

The urbanization of the inland watershed area that has occurred over the past twenty years has likely dramatically increased the amount of sediments and storm water runoff reaching the lagoon area. Prior to urban development of the area, the majority of sediment and stormwater runoff was trapped by the natural vegetation present along the coastal plain prior to reaching the lagoon. Increasing future urbanization of this area would likely increase the volume of both sediment and rainfall runoff reaching the lagoon.

#### 2.5 POTENTIAL CONTAMINATING ACTIVITIES WITHIN WATERSHED

The areas adjacent to Beach and Middle roads contain numerous commercial, residential and industrial facilities that are all potential sources of pollutants to surface and ground waters which impact the lagoon. Potential contaminating activities (PCAs) present in this area include gas stations, garment factories, automobile dealerships, septic systems associated with various residential and commercial properties, and sediment erosion associated with construction and unpaved road erosion. Additionally, the sewer collection system within the project area along Middle Road is known to overflow, and a major new collection system nearing completion along Beach Road will raise the potential for lagoon contamination from sanitary sewer overflows (SSOs).

# 2.6 SITE INFRASTRUCTURES (STORM DRAINS AND SEWERS)

At present, there are 13 storm drainage outlets within the study area that drain to the Saipan Lagoon (Figure 7). The drains were originally installed during construction of Beach Road in the early 1980s. Headwalls for the drain outlets were constructed when the beach walk (bike path) was built in the mid-1990's. A typical storm drain consists of a grated catch basin on the inland side of Beach Road, followed by 30-inch diameter reinforced concrete pipe(s) (RCP) that run beneath Beach Road and convey the storm water from the catch basin to the lagoon. In general, these storm drains collect stormwater from the immediate vicinity of Beach Road (i.e. runoff from Beach Road and properties adjacent to the road). The size of the drainage outlets vary from outlets with one 30" RCP to outlets with three 30" RCPs. The tributaries (areas) for these drains were not delineated during the site visit.

Middle Road parallels Beach Road about a half-mile inland and is similarly drained by a series of individual storm drains. The design of the drains is similar to that of Beach Road with catch basins on the inland side of the road and outlets on the other side of the road. The contributory flow from the upland areas of Middle Road were not delineated or quantitated during the site visit. The drains along Middle Road discharge to the properties between Beach Road and Middle Road. However,

there seems to be no connection between the storm drains on the upper road and those on the lower road. There does not appear to be any drainage easement through this area. Since the topography of the area is relatively flat, runoff tends to pond in the area during heavy rainfall. Depending on the severity of the rainfall event, flooding of the down-slope properties and roads may occur. It appears that only a small fraction of the runoff from properties inland of Middle Road reach the storm drains at Beach Road during normal intensity rainstorms, with the majority of the runoff infiltrating into the highly permeable limestone.

A visual survey of the drainage outlets along Beach Road was conducted. Sediment deposition was observed in the immediate area surrounding the outlets (see site photographs). The deltaic formations around the outlets extended up to 50 feet into the lagoon from these discharge points. The transported sediment consisted of fine sand with some silt and was significantly darker in color than adjacent beach sand.

At present, the homes and businesses within the study area limits are not sewered and use septic systems for disposal of wastewater. No records were available describing the number and location of septic systems in the area. Local regulatory officials suggested that some gray water disposal is discharged directly to the surface without benefit of a septic system or leach field. It is believed that septic system failures probably contribute a significant amount of nutrients to the nearshore waters within the project area.

The Commonwealth Utilities Commission (CUC) is presently constructing a gravity sewer system for the area. Figure 8 shows the general layout of the sewers as shown in the CUC Sewer Master Plan for the area. The main trunk line for the new sewer will run along Beach Road with a number of laterals connecting from the side streets and private properties. Due to topography, lift (pump) stations will be required at certain points in the conveyance system. The new sewer will connect into the existing system in Garapan with the ultimate destination of the wastewater being the Sadok Tasi Wastewater Treatment Plant (WWTP) to the north. PVC pipe will be used for the new sewers.

Sanitary sewer overflows (SSOs) have been reported for the existing wastewater collection system. However, no records have been kept that detail the frequency, location, quantity, cause, and affected area. The only information available is a trouble call log. There have been reports that some overflows have caused wastewater to be discharged into the nearshore marine environment. According to local personnel familiar with the system, the major causes for SSOs have been reported to be:

- Failure of the pumps at the lift stations due to clogging of the impellers.
- Capacity of the collection system exceeded during storm events. During storm events, the collection systems have on occasion received excessive Infiltration and Inflow (I/I) causing them to back up and overflow. I/I in the system can be attributed to a number of factors.

- Large portions of the existing collection systems in the Chalan Kanoa/Kobler Area and the Garapan Area were constructed in the early 70s. The original sewers were constructed using vitrified clay pipe (VCP). The age of the sewer along with the pipe material may give cause for concern for cracks, leaks, and structural damage.
- The sewers are located in areas that have a shallow groundwater table. Some of the sewers are located below the groundwater table lending for a higher possibility of infiltration.
- Localized flooding during storm events may lead to inflow at different points in the collection system (manholes, lift station wet wells, etc.).

#### 2.7 SOCIOECONOMIC CONSIDERATIONS

Saipan's population has increased over four fold between the 1970's to current levels. Much of the population increase occurred in the 1980's as a result of a burgeoning Asian tourist market. Unfortunately, the level of tourism has substantially decreased since the beginning of the Asian crisis in 1997.

In addition to tourism, Saipan's economy is based heavily upon light industrial (garmet factory) production. As a US protectorate nation, merchandise manufactured in Saipan may be sold with a "Made in the USA" label. This affords a marketing benefit for these products in the United States. Much of the work force in these garment factories are foreign (primarily Chinese) contract workers who retain neither residency or citizenship in Saipan. Land ownership in Saipan is limited to persons of indigenous origin. Therefore land ownership is an extremely important factor in the socioeconomic system of the island. Remedial measures that require conversion of private lands to public may prove difficult to implement. In addition, knowledgeable personnel interviewed while on Saipan suggested that whatever remedial measure is recommended should require low maintenance to assure long term success.

A number of scientific studies have been conducted on the island of Saipan over the past three decades. Many of the previous studies involved studying the biological communities and sediment contaminant levels present within the offshore environment. The data generated during these previous studies is summarized in the following sections. The final section in this chapter (Section 3.6) lists the additional environmental, hydrologic and biological studies required to establish baseline conditions existent in the project watershed prior to the initiation of remedial activities.

#### 3.1 PREVIOUS ENVIRONMENTAL INVESTIGATIONS

A number of environmental investigations have been conducted on Saipan at formerly used defense sites created by the U.S. military during and shortly after World War II. These sites are currently being investigated by the USACE under the Defense Environmental Restoration Program: Formerly Used Defense Sites (DERP-FUD). No specific DERP-FUD project site has been identified within the project limits.

The Division of Environmental Quality (DEQ) and USEPA Region IX conducted limited sediment sampling from six offshore sites located around the municipal dump to the north of the project area in 1987. The sediment samples collected were analyzed for heavy metals and PCBs. An extensive follow-on sediment sampling investigation was recently completed within Tanapag Lagoon in the vicinity of the Puerto Rico dump (Denton et al., 2000). Surficial sediments were collected from 32 nearshore and 9 offshore stations and analyzed for heavy metals, polychlorinated biphenyls (PCBs) and polycyclic aromatic hydrocarbons (PAHs). All sediment samples were taken to a depth of 15 cm using hand-held aluminum corers. Three sediment cores were collected for separate analysis from within a 3-m diameter circle at each station. The sediment samples collected were analyzed for the following 10 heavy metals (Ag, Cd, Cr, Cu, Hg, Ni, Pb, Sn, Zn), the 20 chlorobiphenyls of greatest environmental importance based on their toxicological properties, and 16 common PAH compounds ranging in size from two to six fused aromatic rings.

Slightly elevated mercury and lead levels were measured in the vicinity of a sewer outfall and near the entrance to Saipan Harbor. Moderate levels of tin contamination  $(0.1\text{-}5.0~\mu\text{g/g})$  were observed in sediments collected from nearshore stations. All offshore stations in Tanapag Lagoon were relatively free of PCB contamination with total levels consistently below 1 ng/g. Moderate levels of PCBs were detected in sediments collected from two nearshore stations. This study concluded that PCBs do not pose a major threat to benthic communities in this area at the present time. PAHs were only detected in 33% of all offshore sediment cores compared with 81% from nearshore stations. Total sedimentary PAH concentrations ranged from non-detectable to barely measurable in the majority of offshore samples. Closer to shore, levels were often appreciably higher rising to 2.44  $\mu$ g/g near the docks and 3.23  $\mu$ g/g near the Puerto Rico dump.

Sediment sampling has not been conducted in the lagoon portion of the project site. A limited number of sediment samples should be collected and analyzed, at a minimum, for the same list of constituents evaluated during the recent Tanapag Lagoon investigation. The resulting data will be useful for establishing the baseline concentrations of constituents of concern (COC) present within the lagoon prior to the initiation of remedial activities. It will also be useful to compare the COC levels present in sediments from the project area lagoon with levels detected in sediments collected from the more heavily industrialized Tanapag Lagoon.

#### 3.2 PREVIOUS PHYSICAL OCEANOGRAPHIC STUDIES

The CNMI Marine Monitoring Team assesses the condition of the coral reefs in the CNMI on a regular basis. This periodic survey of the condition of the coral reefs provides a reliable indicator of changes in marine water quality in the nearshore lagoon environment. The pH of the lagoon is slightly lower than the open ocean due to increased carbon dioxide concentrations from biotic respiratory activity. Water temperatures vary from a low of 22°C to the upper thirties in the shallow swash zone along the beach. Even under conditions of no rain or runoff, salinity of the lagoon water varies generally with distance from the shoreline as a function of groundwater input and depth. It is not unusual for shoreline salinity to be several points lower than the full 35ppt ocean salinity typical over the outer coral reef. Terrigenous inputs to the lagoon waters can cause turbidity in lagoon waters due to suspended sediments (Pring-Ham and Kirby 1989). However, according to current studies within Saipan lagoon, these silt loads are apparently rapidly diluted and carried out to the open ocean by currents within the lagoon (USACE, 1980, Randall, et.al. 1987). These currents are powered primarily by the pumping action of breaking waves across the reef and tidal flux, and secondarily by wind and wave set-up along the beach. Resultant currents transport lagoon waters out to the ocean through several well-defined reef passages. During the vast majority of times when there is no runoff, the lagoon waters are typically of exceptional clarity.

The results from these previous oceanographic studies should be combined to produce an estimate of the probable residence time of water within the lagoon.

#### 3.3 PREVIOUS WATER QUALITY STUDIES

The Division of Environmental Quality (DEQ) monitors water quality on a weekly basis at 38 fixed stations located along Saipan's western facing coastal beaches. Six beach sites on the northeast coast of the island and six beach sites on the southeast coast are monitored on a quarterly basis. Eleven sites around Managaha Island are also monitored on a quarterly basis. Three of these monitoring locations (WB 22-Garapan Beach, WB 23-Garapan Drainage and WB 24-Chalan LauLau Beach) are located within the project area. The microbiological and chemical parameters monitored include: temperature, salinity, dissolved oxygen, pH, turbidity, and fecal coliform. DEQ has also just begun to test nutrient levels, including nitrate and reactive phosphate, on a monthly and quarterly basis at a

subset of these sites. The quality of water in Tanapag Harbor was also surveyed by Doty (1977) and M&E Pacific (1980). Nearshore values indicated that nitrate levels were higher in low salinity waters probably reflecting land-derived input to the coastal waters.

DEQ also monitors water quality in private and municipal water wells on a biannual and annual basis. The water quality data for nine wells located within the project watershed are compiled in Table 2. The groundwater present within the areas located on the lagoon side of Middle Road is very brackish and contains relatively elevated nitrate concentrations.

Most microbiological violations on Saipan have occurred in areas with heavy stormwater run-off, sewer overflows and leaking septic systems. Garapan was developed on a low-lying wetland and sewer overflows in this area can create standing pools of contaminated water that act as a continual source of fecal coliform contamination to the lagoon. As a result, the majority of fecal coliform violations tend to occur during the rainy season on Saipan (between July through November). Within the project area, the Garapan Beach monitoring site has had a total of four violations while the Garapan Beach Drainage and Chalan Laulau Beach stations have had three violations. This area also likely has a high density of septic tanks which contributes to nitrate contamination in the nearshore environment.

Water quality measurements of stormwater runoff on Saipan have not been made. However, a study (Zolan, 1981) conducted on commercial and residential areas of Guam may be used as an indicator of which chemical constituents may pose a threat to the lagoon environment in Saipan. This study found that runoff samples collected from commercially developed areas were generally much higher in metals levels than runoff from residential areas. The metals tended to be concentrated in the suspended load of the runoff rather than being present in the form of dissolved metal. Concentrations of mercury, cadmium, and lead in urban runoff occasionally approached or exceeded drinking and surface water quality standards. This study concluded that further analysis of receiving waters, sediments and biota were needed to determine the distribution of metals in Guam's environment.

Stormwater runoff samples need to be collected from the project watershed to evaluate the levels of pollutants entering the lagoon via this pathway. In addition, high frequency water quality monitoring (26 times per year) should be conducted at four sites within the project area that contain a high density of seagrass beds. This monitoring would provide the data required to statistically establish baseline water quality for the dry and wet seasons.

#### 3.4 PREVIOUS FLOOD AND RUNOFF STUDIES

A number of the original wetlands present on Saipan were filled during the Japanese era to provide areas suitable for farming. It is estimated that over 60 percent of the wetlands on Saipan were lost during this period (DEQ, 1999). These changes to the natural land cover led to increased rates of sediment and stormwater runoff from the island.

A large portion of the coastal plain from Garapan to Susupe-Chalan Kanoa is currently subject to flooding. The areas to the north (Garapan) and south (Chalan Kanoa) of the project site tend to be the most heavily impacted by flooding. Flooding within the project area appears to largely consist of localized ponding of excess runoff in the areas surrounding Beach and Middle roads.

Flood control studies completed by the USACE for the western shoreline of Saipan include "Draft Detailed Project Report and Environmental Statement Susupe-Chalan Kanoa Flood Control Study" (1979) and "Draft Detailed Project Report and Environmental Statement for the Garapan Flood Control Project" (1984). Because data was not available for the subject areas in these previous reports, the standard unit storm was assumed using precipitation data derived for Guam's Ugum river Study, and depth-duration curves were based upon State of Hawaii data. The primary causes of flood problems in the coastal plain area are the relatively flat topography, the absence of ponding-infiltration areas, and the lack of suitable outlets to convey runoff to the ocean. Initial development of this area for agricultural purposes undoubtedly eliminated the natural wetlands that would store runoff and promote infiltration. The current high density of urban development in this area is not conducive to re-construction of wetland areas.

Three measures to alleviate flooding in the Garapan area were given serious consideration in the USACE studies. Each of these measures involved structural improvements consisting of a diversion channel to convey floodwaters to an outlet channel that would discharge the flow into Saipan Lagoon. The proposed diversion channel was 15 to 20 feet wide at its base and the outlet channel widths varied from 40 to 50 feet. The preferred flood control plan identified by USACE required construction of a 5,720 foot long channel that would discharge into the lagoon near Tanapag Harbor, leaving the lagoon waters fronting Garapan and Puntan Muchot free from flood water input. However, the recommended plan has several inherent problems including:

- The potential for disturbing unknown subsurface historic sites;
- Potential alteration of remaining wetland sites;
- Strong opposition from the National Park Service to construction of one outlet channel through a portion of the American Memorial Park;
- Opposition from the CNMI Department of Natural Resources because the channel traverses a wetland and may endanger birds in the area; and
- Concern about the unknown environmental impact of adding a large flux of flood waters at a single point discharge into Saipan Lagoon

The United States Geological Survey (USGS) maintained a stream gage within the Talufofo Watershed for a number of years (Van der Brug, 1985). Aside from this locality, there are no other perennial streams on Saipan. The Soil Conservation Service has prepared a soil map for the island of Saipan. This document also contains permeability and erosion rates for Saipan soils.

The National Resources Conservation Service (NRCS) conducted an extensive flood and runoff study for the Kagman watershed, on the eastern side of Saipan. Stormwater runoff rates were calculated for this watershed using a Soil Conservation Service computer model that was calibrated to the USGS gage results obtained from the South Fork of Talufofo Stream. Sediment budgets for the area were calculated using the Universal Soil Loss Equation (USLE) and Sediment Delivery Ratios (SDR).

A detailed flood and runoff study has not been conducted for the project area. A study using a similar technical approach utilized by NRCS should be conducted for this area so that peak discharge volumes and sediment loads entering the lagoon environment can be calculated.

# 3.5 PREVIOUS MARINE BIOLOGICAL SURVEYS IN LAGOON AREA

Saipan has had a number of biological surveys conducted by a variety of highly qualified observers during the past half century. Beginning in the 1950's, Schultz and others (Shultz, et.al., 1953, Cloud, 1959) characterized the richness of the tropical coral reef fish assemblage and shoal-water ecology in Saipan. In the 1970's numerous studies were completed, primarily through individuals associated with the University of Guam Marine Laboratory, concerning the abundance of algae (Tsuda & Tobias, 1977; Fitzgerald, 1987), calcareous coraline algae (Gawell, 1974), and reef fishes. In 1977 a study of the harbor area near the proposed mooring site of a power barge brought together a wealth of information regarding the abundance of marine resources present even in an area considered by many to be degraded (Doty & Marsh, 1977). Much of the above works are summarized by Amesbury (Amesbury, et.al., 1979) who defines habitat types and characteristics for Saipan Lagoon. The first general atlas of marine resources of Saipan Lagoon based largely on the habitats defined by Amesbury was completed by Eldridge in 1980. Several other reports, typically requisitioned as a result of specific development proposals, have added significantly to the substantial base of marine biological knowledge of this resource, including a marine survey of the northern Tanapag Reef (Randall et.al., 1987). Much of this information on lagoon habitats and distribution has been digitized and included in the government's GIS database. Given the abundance of background and baseline information, it is fortunate that the CNMI Government and Division of Environmental Quality (DEQ) has established through the CNMI Marine Monitoring Team a program of regular reef monitoring surveys. These surveys will continue to be of great importance for monitoring changes to the reef ecosystem brought about by changes in the water quality of the lagoon.

# 3.6 IDENTIFICATION OF DATA GAPS FOR PROECT AREA

The review of previous biological and environmental studies conducted on Saipan identified a number of additional studies required to adequately establish baseline environmental conditions within the lagoon. These studies should be completed prior to the initiation of remedial measures

within the project area so that the effectiveness of these measures can be evaluated in the future. Each of the recommended studies is discussed in greater detail in Section 4.

The following additional studies are required to establish baseline environmental conditions present within the project area:

- Stormwater Quality Investigation
- Analyze Lagoon Sediments for Physical and Chemical Parameters
- Marine Habitat Mapping from Historical and Current Aerial Photographs
- Inshore Lagoon Area Seagrass and Associated Fauna Survey
- Inventory of Potentially Contaminating Activities in Watershed
- Hydrologic Study of Runoff Processes in Watershed
- Groundwater Level Investigation in Watershed
- Lagoon Water Quality Investigation
- Sanitary Sewer Overflow Assessment of Project Area Collection Systems
- Residence Time Study of Lagoon Water

The studies recommended in this section were selected to provide baseline information on the environmental conditions present within the lagoon and contributory watershed as well as the quality and quantity of runoff entering the lagoon. The data generated by these studies will be combined with the existing site data discussed in Section 3 and can be used to refine the design of future remedial measures. A number of the studies recommended below involve collecting baseline environmental data for the measurable aquatic ecosystem unit proposed for monitoring (i.e., seagrass habitat).

#### 4.1 STORMWATER QUALITY INVESTIGATION

Storm water quantity and quality should be investigated and correlated with rainfall and up-slope land use. Samples and volume estimates should be collected from drainage outlets number 1, 4 and 13 (Figure 7) along Beach Road, and drainage outlets located along Middle Road. A minimum of two rounds of sampling should be conducted, preferably corresponding to storm events occurring during both the dry and wet seasons. If possible, the stormwater sample should be collected within the first half inch of runoff. This is consistent with the "first flush" concept that holds that the first half inch of runoff from any given event will carry 95% of the pollutants transported as a result of that event. Approximate stream flow rates should be measured at the time the stormwater sample is collected. An attempt will be made to measure the total volume of suspended sediment transported during the two monitored storm events by surveying the height and extent of the deltaic deposits that form around the major storm drains after large rainfall events. The stormwater samples should be analyzed, at a minimum, for suspended sediment load, nutrients, pH, turbidity, fecal coliform bacteria and priority pollutant metals. The exact list of constituents of concern (COC) monitored will be based upon the results of the Potentially Contaminating Activities (PCA) survey (Section 4.5), which will identify the types of chemical pollutants that may exist within the watershed.

This investigation will generate useful information on the sediment and nutrient loads entering the lagoon environment. This data will also be useful for future Total Maximum Daily Load (TMDL) studies required for future updates to the island of Saipan's Water Quality Management Plan.

# 4.2 ANALYZE LAGOON SEDIMENTS FOR PHYSICAL AND CHEMICAL PARAMETERS

Lagoonal sediments need to be investigated since they act as major sinks for many of the more persistent and potentially toxic organic and inorganic chemicals introduced into the aquatic environment (Ingersoll 1995). Sediment chemical data provides useful data for evaluating the environmental quality of the lagoon environment and will provide and invaluable baseline for future studies. Sediment samples should be collected along three transects oriented parallel to the shoreline in the lagoon (Figure 9). A total of six composite samples should be collected along each transect.

The sampling locations will roughly correspond to the locations of the six largest stormwater runoff drainage outlets located along the shoreline within the study area. The samples should be collected to depths of 15 centimeters using hand-held aluminum corers. Three separate sediment samples will be collected from a five-meter circular area at each sampling location and combined to generate a single composite sample for analysis. The sediment samples will be analyzed, at a minimum, for grain size, organic carbon content, metals (Ag, Cd, Cr, Cu, Hg, Ni, Pb, Se, Sn, Zn), the 20 chlorobiphenyls of greatest environmental importance based on their toxicological properties, and 16 common PAH compounds ranging in size from two to six fused aromatic rings. Additional COC's may also be analyzed depending on the results of the PCA survey (Section 4.5). The chemical data generated during this study will be compared to the contaminant levels recently measured in sediments collected from Tanapag lagoon (Denton et al, 2000).

# 4.3 MARINE HABITAT MAPPING FROM HISTORICAL AND CURRENT AERIAL PHOTOGRAPHS

Coral communities, algae beds, and shorelines are not static systems; they naturally change over time in response to their surroundings. There are multiple sources of aerial photographs of the Saipan Reef extending back to World War II. In 1980, Eldridge and Randall used a set of USGS photographs to provide the first base maps of the lagoon communities. Amesbury and others have used these maps and supplemental ground observed information to produce the various habitat maps and descriptions presently in use. More recently the USGS, NOAA, and NASA have completed additional photographs and multi-spectral images from various platforms. These map resources should be compiled and compared to the older aerial maps. Information can be obtained relating to shifts in coral colonies, algae abundance, and shoreline erosion and accretion. This information would be invaluable to resource managers charged with the long-term management of resources for future generations.

## 4.4 INSHORE LAGOON AREA SEAGRASS AND ASSOCIATED FAUNA SURVEY

There is presently an adequate mechanism in place for the monitoring of the coral reef and lagoon habitats in the project area. However, the first ecosystem likely to be impacted by lower water quality will be the inshore seagrass habitats and associated fauna. This information gap needs to be filled as soon as possible and the results compared to previous surveys to document the extent of historical change to this habitat.

Thereafter, a simple monitoring strategy for the segrass habitats must be developed that can be successfully undertaken by the CNMI Marine Monitoring Team on a regular and systematic basis. This seagrass monitoring program will be the primary tool used to measure the effectiveness of any

environmental resource remediation strategies implemented as a result of this project, such as implementation of best management practices for sewer line maintenance.

## 4.5 INVENTORY OF POTENTIALLY CONTAMINATING ACTIVITIES IN WATERSHED

Potential contaminating activities (PCAs) that reside within the watershed should be inventoried. Some examples of PCAs on Saipan that should be inventoried include fuel storage facilities such as gas stations, garment factories, septic systems, leach fields, sanitary sewer overflow points, automotive repair facilities, cattle feed lots, intensive agriculture activities, underground and aboveground fuel storage units, and dry cleaning or large-scale laundry operations.

A generic list of PCAs and their associated contaminants should be created. The PCA list will include known sources of contamination, significantly high-risk activities, and other activities that will require a field evaluation during the inventory process. The PCAs will be grouped into categories of Very High, High, Medium, and Low reflecting their relative potential to contaminate the lagoon waters. Factors that will be considered when placing a PCA into a certain category include: 1) the nature of the activity, 2) contaminants associated with the activity, and 3) association with historical incidents of groundwater contamination. A list of chemicals associated with individual PCAs should also be created. This list will be used to associate particular contaminants of concern with each specific type of PCA identified within the watershed.

The PCA inventory will yield an inventory of potentially contaminating sources present within the watershed at the present time. By collecting this baseline information, future changes in chemical loading to the lagoon environment can potentially be related to future changes in land use within the watershed. This information will also be used to finalize the list of chemicals monitored during the stormwater quality (Section 4.1) and sediment analysis (Section 4.2) studies.

## 4.6 HYDROLOGIC STUDY OF RUNOFF PROCESSES IN WATERSHED

A hydrologic analysis for the project watershed is required. This analysis will provide estimates of watershed yield and peak discharges to the shoreline. This hydrologic data is required to properly design storm water quality facilities (e.g. sedimentation basins) so that the sediment retention efficiencies can be obtained.

The first step in the analysis is to delineate and map the various watersheds within the project area. Individual watershed areas will likely need to be sub-divided into smaller subareas of comparatively homogeneous slope, soil and vegetative cover. These areas would then be grouped and erosion rates calculated on the basis of land use, soil, and slope within each subarea. Peak discharges for the project watersheds will be estimated by using an appropriate computer model. Sediment budgets for the areas that contribute to stormwater discharge along the shoreline should be prepared using the Universal Soil Loss Equation (USLE) and site-specific Sediment Delivery Ratios (SDR). The USLE

computes average annual erosion rates. The model results will be calibrated using the suspended sediment loads measured during the two rainfall events monitored for the stormwater quality investigation (see Section 4.1).

### 4.7 GROUNDWATER LEVEL INVESTIGATION IN WATERSHED

The direction and gradient of groundwater flow within the watershed should be determined. This data will be used to estimate the discharge rate of groundwater along the shoreline within the project area. Approximately 25 wells are located within the project watershed. The elevations of up to eight of these wells should be surveyed (Figure 10). Synoptic water level measurements should then be made at these wells and at a lagoon monitoring site (the Fishing Base Pier) over a three-day period. Fluctuations in water levels in the coastal wells due to tides will require that pressure transducers be used to accurately determine the average regional water levels over a minimum three-day period. The hydrologic information collected will be useful for optimizing the design of future stormwater re-injection or infiltration systems. The data will also allow a more accurate estimate of the flux of groundwater that enters the nearshore lagoon within the project area.

### 4.8 LAGOON WATER QUALITY INVESTIGATION

In order to achieve better spatial coverage within the project shoreline area, additional sampling is recommended at new shoreline sampling locations. This data will augment the existing data being collected by DEQ at sites WB 22, WB 23 and WB 24 (Figure 11). Sampling should be augmented to include four areas along the length of the project area; three samples should be collected from each area; one at the shoreline, one beyond the seagrass beds at the surface, and one beyond the seagrass beds near the bottom. Information on tide, wind direction, swell height, and current speed and direction should also be acquired. Samples should be taken at early morning every other week for one year and on a daily basis following at least two storms coincident with the storm water sampling project. This data will allow for the computation of a log-normal statistical baseline for the dry season, wet season, and include variance for storm runoff. In addition a salinity/temperature probe should be used during dry weather and low tide to map salinity temperature profiles along the project shoreline over a period of one tidal cycle. This data will allow a more accurate calculation of residence time within the lagoon and help locate groundwater input sites along the shoreline.

# 4.9 SANITARY SEWER OVERFLOW ASSESSMENT OF PROJECT AREA COLLECTION SYSTEMS

It is suspected that a significant amount of the nutrient and bacteriological contamination along the shoreline arises from overflows and leakage from the sewer system. Although the sewer system within the project area is currently being installed and is not expected to have overflow problems, a

sanitary sewer overflow (SSO) study of the collection systems in Garapan and Chalan Kanoa should be conducted. The major concern being backups in the older collection systems in Garapan and Chalan Kanoa can lead to backups and SSOs within the new sewers of the project area.

At present, there are no official records kept on SSOs that document the frequency, location, quantity spilled, cause, and affected area. In addition, no records are kept on the frequency of sewer line maintenance and pump station maintenance. This information is important because it helps to identify the problem areas in the collection system, the different types of problems, and the severity of the problems. As a first step, information/data of this type should be collected for all SSOs and maintenance activities and stored in a historical database.

After a reasonable amount of data is collected (approximately one to two years), problem areas can be identified and prioritized. Depending on the nature of the problem identified, a number of different types of studies may be conducted for a particular problem area. Some of the different types of studies that may be conducted include the following:

- Closed circuit television inspection of the sewer lines. This type of inspection is useful in identifying the structural condition of the pipe (i.e. cracks and broken pipes), infiltration points, and problem sources (i.e. grease, roots, and structural damage).
- Infiltration and inflow (I/I) study. This type of study is used if excessive I/I is suspected. It is useful in identifying the approximate location and quantity of I/I sources. It may be helpful in identifying areas that require CCTV inspection.
- Capacity analysis of the collection system. This type of study helps to identify areas in the
  collection system (i.e. pump station and trunk lines) that need to upgraded because the
  existing capacity is exceeded due to increased flow rates from collection system expansion or
  increased wastewater generation.

The results from these studies will allow the government to focus future expenditures of limited infrastructure maintenance funds on those sections of the sewer system that are creating the most environmental damage.

# 4.10 RESIDENCE TIME STUDY OF LAGOON WATER

At least two studies of current speeds and patterns within the lagoon have been conducted. The original data from these studies needs to be obtained and integrated with bathymetric charts to calculate the residence time of water at various points within the lagoon. These results need to be combined with storm water inflow calculations to determine the probable concentrations and residence time of pollutants within the lagoon. This number is necessary to determine the total maximum daily load of pollutants that can be allowed to enter the lagoon through point and non-

point sources without damaging the reef ecosystem. This calculation is also useful for the design (sizing) of storm water retention basins.

### 4.11 RANKING OF PROPOSED ADDITIONAL INVESTIGATIONS

The studies recommended in this section are listed in Table 3 according to three categories: relative importance of study for addressing existing data gaps, the relative cost of the study, and the estimated duration of the study. While all of the recommended studies are required to provide missing baseline data prior to the initiation of remedial activities, some of the studies are deemed more critical than others. Cost is also a consideration since only a limited budget exists for the second phase of this study.

The estimated cost of these studies has been classified into three categories: Low, Medium, and High. Low cost studies are estimated to cost less than \$20,000, medium cost studies between \$20,000 and \$60,000, while high cost studies greater than \$60,000 to complete. The relative duration required to complete the recommended studies is also estimated in this table. Short duration studies are estimated to require less than one month to complete. Medium duration studies are estimated to require between one and four months to complete while long duration studies would take between four to twelve months.

Meetings were held in Saipan in early March 2001 with representatives of the U.S. Army Corps of Engineers, Environet, CNMI Department of Environmental Quality and CNMI Department of Public Works. Several decisions arose out of these meetings regarding which studies that would be conducted during the Phase II portion of this project. It was decided that three of the proposed studies, Groundwater Level Investigation in Watershed (Section 4.7), Sanitary Sewer Overflow Analysis (Section 4.9), and Residence Time Study of Lagoon Water (Section 4.10), while important, were not critical to the completion of this project. In addition, DEQ offered to assist the Corps and their Contractors in collecting samples and data for some of the remaining studies. In particular, DEQ has agreed to assist with sample collection and monitoring for those tasks that require working in the lagoon. DEQ will assist the Corps contractor with collecting samples for the Stormwater Quality Investigation (Section 4.1) and the Lagoon Sediment Analysis (Section 4.2). DEQ will also conduct the nearshore lagoon sea grass and fauna surveys (Section 4.4) and will provide runoff observations for the Hydrologic Study of Runoff Processes in Watershed study (Section 4.6).

One of the primary causes of nearshore marine water quality degradation or contamination is storm water runoff carried to the shoreline through natural or man-made drainage structures or via overland flow. Other contributing factors include inadequate infrastructure (e.g., sewage overflows), and accidental spills or leaks of contaminants from industrial facilities located near the shoreline. An environmental restoration program must address each of these potential sources to be successful. Once remedial measures are implemented, the resultant improvements in water quality will increase the nearshore fish population (by improving their habitat) and reduce the frequency of beach closures to public recreational uses.

Several alternatives are discussed below that, if implemented, may improve the water quality and aquatic habitat present in the nearshore lagoon environment in the project area. The alternatives under preliminary consideration include regulatory considerations, improved watershed management, and undertaking infrastructure improvements to reduce the amount of sediments and contaminants that discharge into the ocean. These alternative were tentatively identified by EI based on the limited environmental data currently available and may be changed or modified as more data becomes available. Regulatory considerations are briefly reviewed because they form the basic legal framework under which the studies proposed in Section 4 and tentative restoration alternatives presented in Sections 5.2 and 5.3 should be completed. The U.S. Army Corps of Engineers cannot assist the Saipan government in funding activities related to regulatory compliance. Implementation of regulatory measures and development of public education programs and a watershed management plan are the local governments responsibility.

An important task that must be completed prior to implementing any restoration project is to collect sufficient data to establish existing environmental conditions. This data will help determine appropriate restoration measures and establish a baseline for monitoring the progress of future environmental restoration work. Section 4 provides a discussion of proposed studies that will address the deficiencies in the existing environmental data available for the western shoreline of Saipan.

### 5.1 REGULATORY CONSIDERATIONS

There are a number of federal regulations and programs that address, either directly or indirectly, nearshore water quality issues. Implementation of these regulations will require additional personnel and resources, and a strong commitment from the CNMI government to enforce the regulations. The CNMI government has enacted some regulations, such as the DEQ Earthmoving and Erosion Control Permit, that will potentially improve nearshore water quality. Compliance with the permit requirements is monitored by DEQ.

The primary water quality regulations are promulgated under the Clean Water Act (CWA), which required States and territories, including the CNMI, to promulgate water quality standards. Section 319 was added to the Clean Water Act in 1987 and established the national Non-Point Source

program. Congress has provided funding under Section 319 to States and tribes for the control of non-point source pollution since 1989. The Non-Point Source program is locally focused and state administered.

The National Pollutant Discharge Elimination System (NPDES) Program under the CWA also requires certain industrial activities, including publicly owned treatment works (POTW), to obtain discharge permits. NPDES also provides nationwide General Permits, which provide permit coverage for certain industrial activities that do not require individual permits, provided the activity complies with the conditions of the General Permits.

On December 8, 1999, EPA published Phase II NPDES permitting requirements for small municipal separate storm systems (MS4) (those serving less than 100,000 persons) and construction sites that disturb one to five acres. The rule allows for the exclusion of certain sources from the national program based on a demonstration of the lack of impact on water quality, as well as the inclusion of others based on a higher likelihood of localized adverse impact on water quality. The regulations also exclude from the NPDES program storm water discharges from industrial facilities that have "no exposure" of industrial activities or materials to storm water. It appears that Saipan is not currently subject to this regulation. However, as population on the island rises and the urban population density increases, the Phase II NPDES permitting requirements may become applicable in the near future.

Other regulations, while not addressing water quality specifically, that may have an impact on nearshore water quality include those promulgated under the Resource Conservation and Recovery Act (RCRA), Toxic Substance Control Act (TSCA), and the Oil Pollution Prevention Act (OPA). RCRA regulations govern the management of hazardous waste and underground storage tanks; TSCA regulates the use and disposal of PCB containing materials; and OPA requires the preparation of spill prevention, control, and countermeasure (SPCC) plans and spill response plans. Compliance with these regulations would reduce the amount of contaminants released into the environment, thereby reducing the amount of contaminants carried to the ocean in storm water runoff.

It should be noted that if federal funding is to be used to conduct water quality restoration projects, the National Environmental Policy Act (NEPA) requires that an Environmental Assessment (EA) for the entire project area on the western side of Saipan be performed. Several of the alternatives outlined in the following section may have a significant impact on the environment. Therefore, more comprehensive Environmental Impact Statements may need to be prepared prior to implementation of some of the remedial alternatives recommended below.

Specific regulatory measures that should be considered to address the problems associated with sediment accumulation and entrained pollutant loads in storm water runoff include:

• Revise existing construction permit requirements so that storm water retention capacity standards are current and appropriate for conditions on Saipan.

- Establish storm water drainage standards for new construction and for upgrades of existing infrastructure.
- Review and enforce existing construction Best Management Plans to reduce runoff and sediment loads from development sites.
- The future drainage master plan update for the island should emphasize construction standards that minimize future sediment discharge to the nearshore lagoon environment.
- Review and update existing erosion and sediment control management guidelines, rules and regulations.
- Explore land use control measures such as limiting the size and nature (i.e., commercial, residential, recreational) of future developments between Beach Road and Middle Road.
- Establish a review process for future developments to ensure that storm water runoff concerns are considered and addressed.

## 5.2 INFRASTRUCTURE IMPROVEMENTS

The following infrastructure improvements should be considered to reduce the volume of sediments and improve the quality of stormwater currently entering the lagoon.

- Construct storm infiltration structures to reduce the amount of runoff that reaches the lagoon. Examples of infiltration structures include injection wells and perforated piping buried under roadways, infiltration trenches and basins. Infiltration facilities rely on the percolation of storm water runoff through surface soils. Pollutants are captured by soil particles as the filtered water percolates down into groundwater. Use of infiltration facilities is dependent on suitable soils and groundwater protection issues. One possible way of establishing an infiltration basin is to construct a multipurpose recreational facility (football, baseball, and soccer fields) between Beach and Middle Roads. The project area is suitable for this type of system due to the high permeability of the coastal sediments. In addition, a properly located infiltration gallery may provide a partial hydraulic barrier to saltwater intrusion for inland, potable well sources (e.g. Gualo Rai wells). An infiltration system patterned after the Guam San Vitores Road project, where a large underground infiltration gallery is placed directly beneath a significant length of either Beach or Middle road, is another possible alternative.
- Construct/install storm water filters such as vegetation filters or physical filters. Examples of
  vegetation filters include tall grass covered drainage swales and vegetation covered marshes
  (wetlands). Examples of physical filters include grates, screens, and rock and sand filters
  designed to trap particles of various sizes that are entrained in storm water.

- Construct small settling ponds up-slope of Beach Road on each major storm drain outlet to reduce the amount of sediment transported to the shoreline. These basins could double as small parks, playgrounds, or parking lots.
- Construct one or two major storm water retention and infiltration basins between Beach Road and Middle Road. Investigate the possibility of these basins doubling in function as soccer, rugby, baseball or other recreational sporting fields and associated facilities.
- Construct diversionary structures to keep clean rainfall away from contaminant sources.
   Examples include diverting rainfall runoff from areas of land disturbance at construction sites.
- Continue with present plans to update, improve, and extend existing sewer system. Establish deadlines to require connection for all waste water systems and abandonment of septic tank and leach field systems located within the project area. Leaks from the existing sewer lines are the suspected primary source of high nitrate levels and fecal coliform that are periodically detected in the lagoon waters. The sewer line study in Section 4.11 provides a discussion of additional information that will be required to implement this alternative.
- Devise engineering controls to minimize failures in pumps at lift stations and improve maintenance of lift stations.
- Road improvements should take into account methods to minimize sediment transport.
   Design curbs to channel flow to infiltration areas and pave existing unpaved roads that are prone to erosion in the coastal zone.

Future infrastructure improvements need to be coordinated with the design requirements developed in the ongoing USACE Saipan Drainage Master Plan and take into consideration projected population growth and urban development on the island. Infrastructure improvements that will likely have an impact on nearshore water quality during construction may require a Section 401 Water Quality Certification (WQC) Form. Section 401 refers to that section in the Clean Water Act, which is regulated by DEQ. A WQC is issued when there is a corresponding federal permit for an activity that may result in water quality degradation. All construction projects on Saipan require a DEQ Earthmoving and Erosion Control Permit which requires "24 hour storage of 25-year, 24-hour storm; or 75% sediment removal rate" for both during-construction stormwater systems and post-construction stormwater systems.

### **5.3 WATERSHED MANAGEMENT**

The rapid rise in population on Saipan over the past two decades has led to increasing urbanization of the island. Urbanization increases overland runoff into the ocean because building and roadway construction decreases open space and permeable land area. Urbanization also increases the amount of pollutants released into the environment from a concentration of people and potential sources, and consequently increases the contaminants that are carried to the lagoon in runoff and via groundwater.

Watershed management involves a combination of regulatory enforcement, infrastructure improvement, and urban planning to reduce the introduction of pollutants to a land area, and to minimize the amount of storm water runoff, which carries the pollutants to the lagoon. The preliminary remedial measures under consideration involve the preparation of a watershed management plan. Components of the plan may include:

- Identify major source areas of sediments entering the lagoon.
- Evaluate the effectiveness of initiating reforestation of currently denuded portions of the
  watershed to minimize soil erosion. Special consideration should be given to native tree,
  shrub, and grass species (this may have the added benefit of reestablishing threatened or
  endangered species).
- Educate the public to reduce unnecessary application of fertilizers, pesticides, and improper disposal of household chemicals.
- Insure better enforcement of existing environmental regulations (see Section 1.4)
- Discuss the possibility of instigating land use control measures such as limiting the size and nature (i.e., commercial, residential, recreational) of future developments, especially in the area between Beach and Middle roads.
- Discuss the need to adopt zoning laws that maximize permeable areas and open spaces within areas undergoing urban development.
- Discuss the need for establishing drainage easements between Middle Road and Beach Road prior to the area becoming even more urbanized.
- Implement recommended infrastructure improvement projects (see Section 5.2).

1	An Executive Summary should be provided at the beginning of this document, no more than 2 pages in length, which briefly states the findings on the suspected causes of lagoon degradation, and the recommendations for regulatory changes, infrastructure	We will add an executive summary to the report
71 11	improvements, watershed management, and additional studies necessary to refine these recommendations.	
2	Section 1.4 (Page 4, 3 <sup>rd</sup> paragraph) – This paragraph describes the definitions of Class A and AA waters in the CNMI, but there are some inconsistencies with the actual regulations that define these classifications. We suggest the following description for Class A and AA marine waters to be more consistent with the wording in our Water Quality Standards:	We will replace the paragraph with the exact wording taken out of the Water Quality Standards.
	The CNMI has designated two classes of marine waters; A and AA. Class AA represents high-quality waters that are considered to be in a "natural" and "pristine" state. The CNMI Water Quality Standards states that "to the extent practicable, the wilderness character of such areas shall be protected", and does not permit any discharge of pollutants in class AA waters. Class A waters have been designated in two parts of Saipan, and generally represent a slightly lower quality of water in which some discharges may be permitted, for example, the two sewage treatment plant outfalls on Saipan. Nevertheless, Class A waters must support recreational use and the propagation of fish, shellfish, and wildlife, and strict water quality standards have been set for the protection of these uses in Class A marine waters Additionally, further protection is afforded through the CNMI Anti-Degradation Policy, which is part of the Water Quality Standards and protects existing uses and water quality in any waters, despite their classification.	
3	Section 2.2 (Page 5, 3 <sup>rd</sup> para.) Beach Road is a two-lane, undivided highway.	We will revise the text.
4	Section 2.2.2 (Page 6, 3 <sup>rd</sup> para.) Add the following underlined word: "The site potentially receives runoff and sediments from the entire West Takpochao watershed"	We will revise the text.

1	Section 2, Part 2.2.2: The study area is the western coastal area of Saipan from Garapan to roughly Chalan Kanoa. The report states the project area receives runoff from the entire west Takpochao watershed which extends roughly 3.5 miles inland. This is a gross overstatement. Mt. Takpochao is only about 2 miles inland from the western coast and the island is barely 3.5 miles wide in this location. There are certainly localized drainage channels which find their way to the sea, but their run in not over a mile. Also, in this same section it is mentioned the soils are uniformly varying from the coast to the uplands. From our experience there are pockets of eroded sediments, clayey areas and karst throughout the area from the coastal area to the uplands. While general soil profiles can describe an	We will revise the text to specifically talk about the watershed area that contributes runoff to only the project area, which extends from Quartermaster Road to the Fishing Base. We will also add a comment about the small scale heterogeneity in soil types present throughout the watershed.
	area, within the area the soils can vary widely.	
2	2.2.3: Soil Erosion: In my opinion significant soil erosion is from unpaved secondary road, unprotected building sites, and recently cleared or burned areas.	Agreed.
3	2.4: In contrast to their statement I would consider the eastern side of Beach Road to be densely developed, not characterized by "a few houses present along the few dirt and paved roads that cross between the two main roads" referring to the area between Beach Road and Middle Road.	The comment in the text was meant to refer to the overall area located between Beach and Middle road which is one of the less developed areas along the western coastal plain of Saipan.
4	2.5: This section states the variety of development in the area and contradicts the area previously mentioned as sparsely developed.	We will make the text consistent regarding the density of development in the area.
5	2.6: This section is in contrast to Section 2.2.2 and states that the tributaries for the storm drains "were not delineated during the site visit". Why not, it is not so hard to walk up a drainage channel? The section also states that drainage from "upland areas of Middle Road were not delineated or quantitated during the site visit". And in addition, "there seems to be no connection between storm drains on the upper road and those on the lower road". This is simply not true. The report says ponding prevails after a heavy rainfall and only a small fraction of the Middle Road runoff reaches Beach Road. Obviously, they have never experienced a heavy rainfall and seen the raging rivers crossing Middle Road on their	The purpose of the recomnaissance field visit was to simply identify the relevant issues that require additional study.  Based on our limited observation of runoff after heavy rainfall within the project area, significant amounts of runoff are generated in the vicinity of Middle road, which ultimately flows towards the downhill, ocean side of the road. However, much of this runoff appears to infiltrate within the developed and undeveloped land areas located between Middle road and Beach road prior to reaching the lagoon.

Baseline Monitoring Studies

C.1
Stormwater Quality Investigation

### **APPENDIX C.1**

## STORMWATER QUALITY INVESTIGATION

Stormwater runoff samples were collected from storm drains 4, 6, 11, and 13 located along the shoreline within the study area, Drain 14 located south of the study area, and the Dai Ichi Hotel and Hafa Adai Hotel located north of the study area (Figure C.1). These particular storm drains or drainage areas were chosen for several reasons:

- Drains 4, 6, and 11 typically have a high volume of runoff during rain events, and even flow during small rain events, providing consistent sediment transport to the lagoon. They are also spatially located to provide comprehensive coverage of the study area.
- Drain 13 was chosen because it is located at the intersection of Quartermaster Road and Beach Road. This location provides lateral coverage of the study area and allows for runoff variance between Middle and Quartermaster Roads. This location was only sampled once.
- Drain 14 is located south of the study area in the vicinity of Lake Susupe and its associated wetlands. This location was sampled twice in an effort to determine if the presence of a natural wetland (Lake Susupe) would reduce the sediment/nutrient load transported by stormwater discharge.
- The Dai Ichi Hotel and the Hafa Adai Hotel are located north of the study area. These two locations were each sampled twice to establish potential sediment/nutrient load adjacent to the study area.

Table C.1 provides stormwater discharge volume measurements collected in 2002 from the selected drain locations.

**Table C.1: Discrete Stormwater Discharge Volumes** 

Date	Drain 4 (gpm)	Drain 6 (gpm)	Drain 11 (gpm)	Drain 13 (gpm)	Drain 14 (gpm)		
2/13/02	NS	3	30	NS	30		
5/9/02	NS	1200-1500	200	10	NS		
7/1/02	106	40	15	NS	NS		
7/29/02	5	20	20	NS	NS		
8/12/02	428	1000	150	12	NS		
9/20/02	60	1200	NS	600	NS		

NS = not sampled

gpm = gallons per minute

Flow volumes at each drain vary greatly due to several factors. During small rain events, the amount of rainfall within the watershed determines how much rain affects each drain. For example, it may have rained harder at the northern end of the study area than at the southern end, resulting in more flow at northern drains. Also, the topography of the contributory areas for each drain differs, affecting both the time of concentration and the volume of flow to each drain.

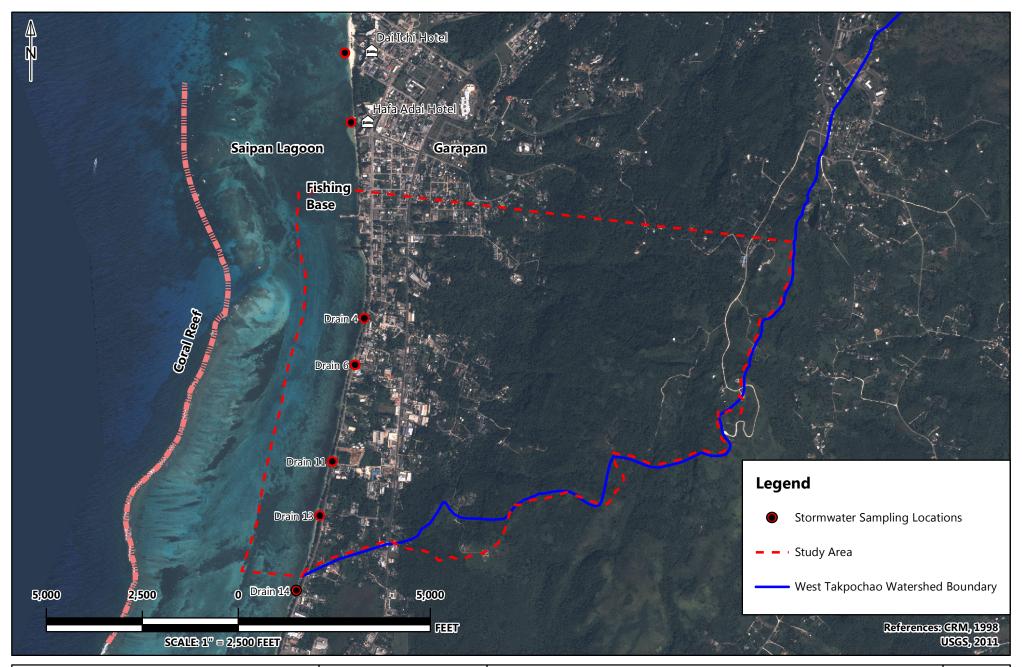

Typically, the initial surface runoff water is the most heavily contaminated during a rain event simply because it transports contaminants that may be present on the ground surface down-slope. An effort was made to collect the runoff samples during the initial flush of the rain events listed above in order to try to capture the most contaminant–laden runoff water. The runoff samples were shipped to Sequoia Analytical Laboratories in Petaluma, California to be analyzed for priority pollutant metals. The complete laboratory analytical reports from these analyses are included at the end of this report. Results are presented in Table C.2.

The runoff sample results were compared against the United States Environmental Protection Agency (EPA) national recommended water quality standards for priority pollutants (EPA, 2009), both chronic and acute toxicity values for the freshwater aquatic life criteria:

- Runoff samples from Drain 4 consistently exceeded the standards for cadmium, copper, lead, and zinc. Selenium was detected at a concentration exceeding the chronic toxicity standard in one of the four samples collected from Drain 4.
- Runoff samples from Drain 6 consistently exceeded the standards for copper. In addition, cadmium and lead were detected at concentrations exceeding the standards in five of seven samples collected from Drain 6. Zinc was detected once at a concentration exceeding the acute toxicity criteria at Drain 6.
- Runoff samples from Drain 11 consistently exceeded the standards for copper. In addition, cadmium and lead were detected at concentrations exceeding the standards in five of six samples collected from Drain 11. Zinc was detected three times at a concentration exceeding the acute toxicity criteria at Drain 11. Nickel was detected once at a concentration exceeding the chronic toxicity criteria at Drain 11.

None of the metals were detected at concentrations exceeding the standards in the single sample collected at Drain 13.

- Zinc was detected at a concentration exceeding the acute toxicity criteria in both samples collected at Drain 14. Copper was detected once at a concentration exceeding the acute toxicity criteria at Drain 14. Cadmium was detected once at a concentration exceeding the chronic toxicity criteria at Drain 14.
- Cadmium and selenium were detected at concentrations exceeding the chronic toxicity criteria in both of the samples collected at the Dai Ichi Hotel. Copper and zinc were detected at concentrations exceeding the acute toxicity criteria in one of the two samples collected at the Dai Ichi Hotel.
- Cadmium and copper were detected at concentrations exceeding the standards in both of the samples collected at the Hafa Adai Hotel. Lead was detected once at a concentration exceeding the chronic toxicity standard at the Hafa Adai Hotel.

Some of the metals were detected at a higher concentration during times when the measured stormwater discharge was higher. This may be an indication that metals that are deposited on the ground surface from anthropogenic sources such as motor vehicles and industrial activities are washed into the lagoon via stormwater runoff during large rainfall events. However, runoff sample exceedances occurred during both the dry and wet season, and the result is not consistent enough to conclude that more metals are carried into the lagoon during larger rainfall events. It may be safer to conclude that the amount of metals that are carried into the lagoon via stormwater runoff depends on the source of contamination (from pervious or impervious surfaces) and the relative timing of the rain event. Stormwater runoffs during early season rains or after a dry period usually contain the highest pollutant concentration due to the amount of time that has allowed pollutants to be deposited and accumulate on impervious surfaces. Pollutants from pervious surfaces on the other hand may be found at a constant rate regardless of the timing of the rain event. Additional data may be required to determine the source of metal pollutants that are washed into the lagoon via stormwater runoff (no additional stormwater data has been collected since 2002). Since this study proposes a solution that will capture contaminated stormwater regardless of the source of metal pollutants, additional study is considered outside the scope of this study.

C.2
Lagoon Sediment Physical and Chemical Parameters

#### APPENDIX C.2

#### LAGOON SEDIMENT PHYSICAL AND CHEMICAL PARAMETERS

Increasing development along the shoreline of Saipan Lagoon has led to an increase in the introduction of potentially toxic pollutants to the lagoon. The Water and Environmental Research Institute of the Western Pacific (WERI) initiated a pollution monitoring and assessment program for the northern half of Saipan Lagoon (Tanapag Lagoon) in 1997 and identified heavy metals as the contaminants of primary concern in this area (Denton et al., 2009; 2008; 2006; 2001).

Sediments are often an accumulation point for potentially toxic organic and inorganic chemicals introduced into an aquatic environment (Ingersoll, 1995). Analytical data derived from sediment samples is often more useful than that from water samples because of the more immobile nature of sediment. Analysis of sediments can yield data that lends valuable insight as to the nature of contaminants entering the aquatic ecosystem from onshore pollutant sources.

As part of an effort to characterize the general distribution and abundance of pollutants in sediments in the study area, a total of 18 surface sediment samples were collected from the lagoon bottom in September 2002. Samples were collected from six transects extending from nearshore to the outer lagoon, stretching the entire length of the study area. The starting point for each transect was established at storm drains 1 (Dai Ichi Hotel), 4 (13 Fisherman Memorial), 7 (Gold Beach Hotel), 11 (China House Restaurant), and 13 (Quartermaster Road) located along the shoreline of the study area as well as a wetland location adjacent to storm drain 14 (Figure C.2).

Each transect included a sample location within the nearshore *Enhalus* beds, within the nearshore *Halodule* band, and within off-shore *Enhalus* beds located beyond the channel. These sampling locations were estimated to be at 250 meters (m), 500 m, and 1000 m from shore. Samples consisted of a composite of surface sediments collected from three discrete locations around each transect point. Each sediment sample was analyzed for priority pollutant metals, polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs), as well as specific PCB congeners known to be found north of the study area in the Tanapag area during the WERI study.

Table C.3, Table C.4, Table C.5, and Table C.6 summarize analytical results for metals, PCBs, PAHs, and PCB congeners, respectively. The final two numerals of each sample number indicate the specific location of the sample. The first of the final two numerals indicates which of the six transects was sampled. The second numeral indicates whether the sample was collected from the nearshore *Enhalus* bed (1), the nearshore *Halodule* band (2), or the seaward, off-shore *Enhalus* bed (3). Laboratory analytical reports for the sediment samples are included at the end of this report.

As a non-regulatory comparison, analytical results of sediment samples were compared to the EPA regional screening levels (RSLs) for residential soil (EPA, 2012). Overall metals concentrations detected in lagoon sediment were low, but analytical results indicate that in general, sediment collected from the nearshore contained slightly higher concentrations of metals

than those samples collected from mid to off-shore locations. Concentrations of arsenic exceeded the EPA RSL for residential soil in some or all of the locations for all six transects. Concentrations of arsenic detected in samples ranged from 5.1 to 12 milligrams per kilogram (mg/kg), compared to the residential RSL of 0.39 mg/kg.

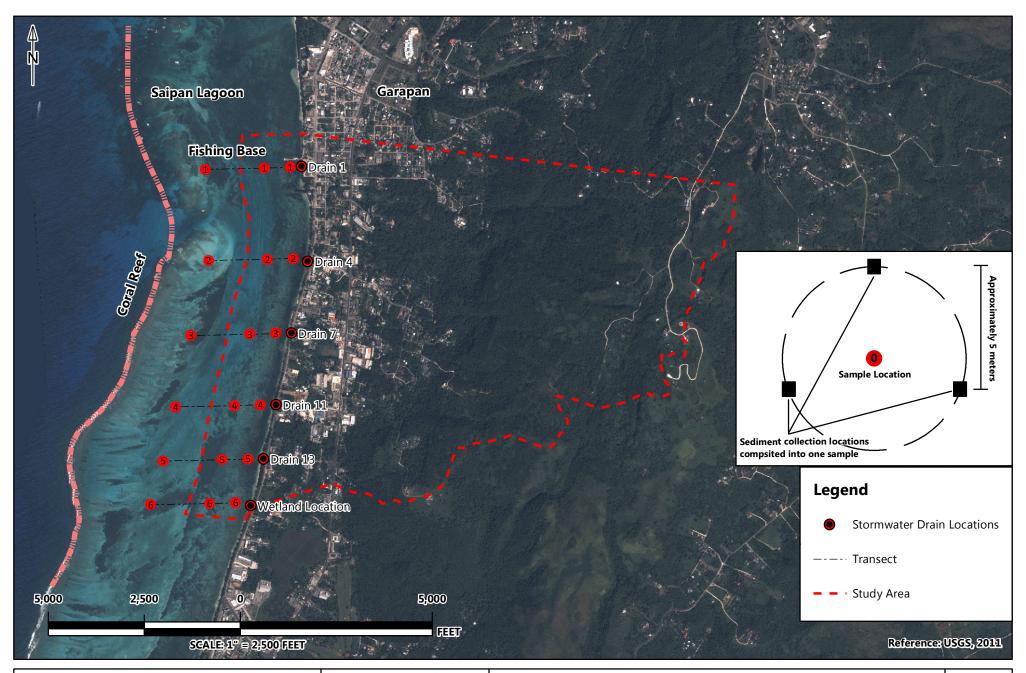

PCBs, PAHs, and PCB congeners were not detected in any of the samples above the laboratory reporting limits. All laboratory reporting limits were below the EPA RSLs except for benzo(a)anthracene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene.

More recent data characterizing the sediment composition of Saipan Lagoon are available from a study conducted by Denton and Starmer (2009) in which sediment samples for heavy metals analysis were collected from 16 of 22 coastal stormwater discharge points that currently exist along the southern half of the lagoon. Surface sediments were collected at offshore locations at 0 m, 10 m, 25 m, 50 m, 100 m, and 250 m from shore along transect lines perpendicular to the discharge points. Samples were also collected from 500 m and 1,000 m offshore where possible. Geometric means were calculated at each distance and the minimum and maximum concentrations were determined. Table C.7 provides a summary of data collected by Denton and Starmer (2009).

Metals concentrations found in surface sediment samples collected in 2009 were all below the EPA RSL, and were similar to those found in sediment samples collected in 2002. The units for the 2002 data are mg/kg and the 2009 data units are micrograms per gram ( $\mu$ g/g), which are comparable without conversions. There are some differences between the metals concentrations found in 2002 and 2009, however these do not follow any major trends and are not significant enough to draw any conclusions.

The maximum concentration of copper in samples collected at 250 m offshore in 2009 (6.47  $\mu g/g$ ) was higher than the maximum concentration of copper found in samples collected at 250 m offshore in 2002 (1.6 mg/kg). The maximum concentration of mercury in samples collected at 250 m (0.1  $\mu g/g$ ) and 500 m (0.0558  $\mu g/g$ ) offshore in 2009 was also higher than the maximum concentration of mercury in samples collected at 250 m (0.015 mg/kg) and 500 m (0.025 mg/kg) offshore in 2002. In addition, the overall range of chromium detected in all samples collected (i.e., samples collected at 250 m, 500 m, and 1,000 m offshore) in 2002 (4.4 to 8.5 mg/kg) were higher than the range in concentration of chromium found in samples collected at 250 m, 500 m, and 1,000 m offshore during 2009 (1.48 to 3.86  $\mu g/g$ ). The maximum concentration of zinc in samples collected at 500 m (2.9 mg/kg) and 1,000 m (2.1 mg/kg) offshore in 2002 was also higher than those collected at 500 m (0.4  $\mu g/g$ ) and 1,000 m (0.4  $\mu g/g$ ) offshore in 2009. The differences of these metal concentrations detected in 2002 and 2009 are likely due to different sample locations that were included in each study.

The 2009 data collection found the highest levels of metals in sediment samples close to shore, as opposed to those collected further offshore. This is in agreement with findings from the 2002 data collection and appears to support the theory that urban runoff is one of the major contributing sources for metal contamination in the lagoon sediment.

Notes:

All units in mg/kg.

<sup>\*</sup> EPA RSL for total chromium is not listed. RSLs for chromium(III) and chromium (IV) are 120,000 mg/kg and 0.29 mg/kg, respectively.

<sup>-</sup> EPA RSL (EPA, 2012): US Environmental Protection Agency Regional Screening Levels, Residential Soil, updated May 2012.

<sup>-</sup> A value followed by "U" indicates that the analyte was not detected at or above the reporting limit.

<sup>- &</sup>quot;J" indicates estimated value.

<sup>-</sup> Bold values exceed the EPA RSL.

#### **Notes and Definitions**

C-01 To reduce matrix interference, the sample extract has undergone sulfuric acid clean-up, method 3665, which is specific to hydrocarbon contamination.

C-06 To reduce matrix interference, the sample extract has undergone TBA (sulfur) clean-up, method 3660B.

HT-03 This sample was extracted beyond the EPA recommended holding time. The results may still be useful for their intended purpose.

HT-04 This sample was analyzed beyond the EPA recommended holding time. The results may still be useful for their intended purpose.

J Estimated value.

QM-RX The spike recovery was outside control limits for the MS and/or MSD due to matrix interference. Re-extraction/re-analysis performed to confirm original MS/MSD results.

RA The result is from re-extraction and re-analysis to confirm original MS/MSD result.

S-BN Base/Neutral surrogate recovery outside control limits. The data was accepted based on valid recovery of remaining two

base/neutral surrogates.

S-LIM The surrogate recovery was outside control limits. The result may still be useful for its intended purpose.

DET Analyte DETECTED

ND Analyte NOT DETECTED at or above the reporting limit

Mr. Matt Neal Environet 2850 Paa Street Suite 212 Honolulu, HI 96819

Re: Laboratory Project No. 22000

SDG: 89891

Dear Mr. Neal:

Enclosed are the analytical results of samples received intact by Severn Trent Laboratories on September 25, 2002. Laboratory numbers have been assigned and designated as follows:

<u>Lab ID</u>	Client Sample ID	Sample <u>Date</u>	Sample <u>Matrix</u>
	Received: 09/25/02	2 ETR No: 89891	
502104	F01009 LS 1,3	09/17/02	Solid
502105	F01009 LS 1,2	09/17/02	Solid
502106	F01009 LS 1,1	09/17/02	Solid
502107	F01009 LS 2,3	09/17/02	Solid
502108	F01009 LS 2,2	09/17/02	Solid
502109	F01009 LS 2,1	09/17/02	Solid
502110	F01009 LS 3,3	09/17/02	Solid
502111	F01009 LS 3,2	09/17/02	Solid
502112	F01009 LS 3,1	09/17/02	Solid
502113	F01009 LS 4,3	09/17/02	Solid
502114	F01009 LS 4,2	09/17/02	Solid
502115	F01009 LS 4,1	09/17/02	Solid
502116	F01009 LS 5,3	09/17/02	Solid
502117	F01009 LS 5,2	09/17/02	Solid
502118	F01009 LS 5,1	09/17/02	Solid
502119	F01009 LS 6,3	09/17/02	Solid
502120	F01009 LS 6,2	09/17/02	Solid
502121	F01009 LS 6,1	09/17/02	Solid

Mr. Matt Neal September 27, 2002 Page 2 of 2

**STL Burlington** 

The continuing calibration sample analyzed on 10/3/02 at 2310 hours exhibited percent differences for BZ#77 and BZ#153 outside of the established quality control limits on the RTX-5 column. Congeners BZ#77 and BZ#118 also yielded percent differences slightly outside of the established quality control limits on the RTX-CLPII column.

If there are any questions regarding this submittal, please contact Chris Anderson at (802) 655-1203.

This report shall not be reproduced, except in full, without the written approval of the laboratory. This report is sequentially numbered starting with page 0001 and ending with page 0094

I certify that this package is in compliance with the NELAC requirements, both technically and for completeness, for other than the conditions detailed above. The Laboratory Director or his designee, as verified by the following signature has authorized the release of the data contained in this hardcopy data package.

Sincerely,

, for: Michael F. Wheeler, Ph.D.

Laboratory Director

### **PCB CONGENER ANALYSIS**

### Qualifier Definitions:

- U= Compound not detected above reporting limit.
- J= Compound reported at an estimated concentration below the reporting limit.
- E= Compound reported at an estimated concentration which exceeds the calibration range.
- S= Specific column result used for quantitation due to confirmation column coelution.
- T= Tentative identification, specific column result used with no confirmation information.
- X= Estimated concentration due to coelution on both columns.
- P= Confirmation column result exceeds reported result by more than 25%.
- H= Specific column or estimated result exceeds confirmation result by more than 25% despite expected confirmation coelution.
- B= Compound detected above reporting limit in method blank.
- N= Compound does not comply with initial and/or ongoing calibration criteria.

### STL Burlington - Target GC Injection Report

Flags: A - Peak quantitates above calibration range

- a Peak quantitates below reporting limit
- H User selected alternate compound hit
- $\ensuremath{\mathrm{M}}$  Peak manually integrated or manually identified
- R Peak fails recovery
- ${\tt U}$  User disabled peak  ${\tt ID}\colon$  either peak quantitates below reporting limit or peak identification not confirmed on second column

Flags: A - Peak quantitates above calibration range

a - Peak quantitates below reporting limit

H - User selected alternate compound hit

M - Peak manually integrated or manually identified

R - Peak fails recovery

U - User disabled peak ID: either peak quantitates below reporting limit or peak identification not confirmed on second column

Flags: A - Peak quantitates above calibration range

a - Peak quantitates below reporting limit

H - User selected alternate compound hit
M - Peak manually integrated or manually identified

R - Peak fails recovery

U - User disabled peak ID: either peak quantitates below reporting limit or peak identification not confirmed on second column

Flags: A - Peak quantitates above calibration range

0079

a - Peak quantitates below reporting limit
H - User selected alternate compound hit

M - Peak manually integrated or manually identified

R - Peak fails recovery

U - User disabled peak ID: either peak quantitates below reporting limit or peak identification not confirmed on second column

Flags: A - Peak quantitates above calibration range

- a Peak quantitates below reporting limit
- H User selected alternate compound hit
- $\ensuremath{\text{M}}$  Peak manually integrated or manually identified
- R Peak fails recovery
- U User disabled peak ID: either peak quantitates below reporting limit or peak identification not confirmed on second column

#### FORM 1 OTHER ORGANICS ANALYSIS DATA SHEET

ENVNET SAMPLE NO.

F01009LS33

Lab Name: STL BURLINGTON

Contract: 22000

Lab Code: STLVT Case No.: 22000 SAS No.:

SDG No.: 89891

Matrix: (soil/water) SOIL

Sample wt/vol:

Lab File ID: 030CT021608-R101

% Moisture: 25 decanted: (Y/N) N

30.0 (g/mL) G

Date Received: 09/25/02

Lab Sample ID: 502110

Extraction: (SepF/Cont/Sonc) SOXH

Date Extracted: 09/26/02

Concentrated Extract Volume: 10 (mL)

Date Analyzed: 10/04/02

Injection Volume: 1.0(uL)

Dilution Factor: 1.0

GPC Cleanup: (Y/N) N pH: \_\_\_

Sulfur Cleanup: (Y/N) Y

CONCENTRATION UNITS:

CAS NO.

Flags: A - Peak quantitates above calibration range

- a Peak quantitates below reporting limit
- H User selected alternate compound hit
- M Peak manually integrated or manually identified
- R Peak fails recovery
- U User disabled peak ID: either peak quantitates below reporting limit or peak identification not confirmed on second column

Flags: A - Peak quantitates above calibration range

- a Peak quantitates below reporting limit
  H User selected alternate compound hit
- $\ensuremath{\mathrm{M}}$  Peak manually integrated or manually identified
- R Peak fails recovery
- U User disabled peak ID: either peak quantitates below reporting limit or peak identification not confirmed on second column

### FORM 1 OTHER ORGANICS ANALYSIS DATA SHEET

ENVNET SAMPLE NO.

F01009LS41

Lab Name: STL BURLINGTON

Contract: 22000

Lab Code: STLVT Case No.: 22000 SAS No.:

SDG No.: 89891

Matrix: (soil/water) SOIL

Lab Sample ID: 502115

Sample wt/vol:

30.0 (g/mL) G

Lab File ID: 030CT021608-R181

% Moisture: 27 decanted: (Y/N) N

Date Received: 09/25/02

Extraction: (SepF/Cont/Sonc) SOXH

Date Extracted: 09/26/02

Concentrated Extract Volume: 10(mL)

Date Analyzed: 10/04/02

Injection Volume: 1.0(uL)

Dilution Factor: 1.0

GPC Cleanup: (Y/N) N pH: \_\_\_\_

Sulfur Cleanup: (Y/N) Y

CONCENTRATION UNITS:

CAS NO.

COMPOUND

## FORM 1 OTHER ORGANICS ANALYSIS DATA SHEET

ENVNET SAMPLE NO.

F01009LS42

Lab Name: STL BURLINGTON

Contract: 22000

Lab Code: STLVT Case No.: 22000 SAS No.:

SDG No.: 89891

Matrix: (soil/water) SOIL

Lab Sample ID: 502114

Sample wt/vol:

30.0 (g/mL) G

Lab File ID: 030CT021608-R171

% Moisture: 29 decanted: (Y/N) N Date Received: 09/25/02

Extraction: (SepF/Cont/Sonc) SOXH

Date Extracted: 09/26/02

Concentrated Extract Volume: 10 (mL)

Date Analyzed: 10/04/02

Injection Volume: 1.0(uL)

Dilution Factor: 1.0

GPC Cleanup: (Y/N) N pH:

Sulfur Cleanup: (Y/N) Y

CONCENTRATION UNITS:

CAS NO. COMPOUND

## FORM 1 OTHER ORGANICS ANALYSIS DATA SHEET

ENVNET SAMPLE NO.

F01009LS43

Lab Name: STL BURLINGTON

Contract: 22000

Lab Code: STLVT Case No.: 22000 SAS No.:

SDG No.: 89891

Matrix: (soil/water) SOIL

Lab Sample ID: 502113

Sample wt/vol: 30.0 (g/mL) G

Lab File ID: 030CT021608-R161

% Moisture: 32 decanted: (Y/N) N Date Received: 09/25/02

Extraction: (SepF/Cont/Sonc) SOXH

Date Extracted: 09/26/02

Concentrated Extract Volume: 10(mL) Date Analyzed: 10/04/02

Injection Volume: 1.0(uL)

Dilution Factor: 1.0

GPC Cleanup: (Y/N) N pH: \_\_\_

Sulfur Cleanup: (Y/N) Y

CONCENTRATION UNITS:

CAS NO. COMPOUND

(ug/L or ug/Kg) UG/KG

Flags: A - Peak quantitates above calibration range

- a Peak quantitates below reporting limit
- H User selected alternate compound hit
- M Peak manually integrated or manually identified
- R Peak fails recovery
- U User disabled peak ID: either peak quantitates below reporting limit or peak identification not confirmed on second column

Flags: A - Peak quantitates above calibration range

a - Peak quantitates below reporting limit

H - User selected alternate compound hit

M - Peak manually integrated or manually identified

R - Peak fails recovery

U - User disabled peak ID: either peak quantitates below reporting limit or peak identification not confirmed on second column

Flags: A - Peak quantitates above calibration range

- a Peak quantitates below reporting limit
- H User selected alternate compound hit
- M Peak manually integrated or manually identified
- R Peak fails recovery
- U User disabled peak ID: either peak quantitates below reporting limit or peak identification not confirmed on second column

Flags: A - Peak quantitates above calibration range

.

67 0150

a - Peak quantitates below reporting limit

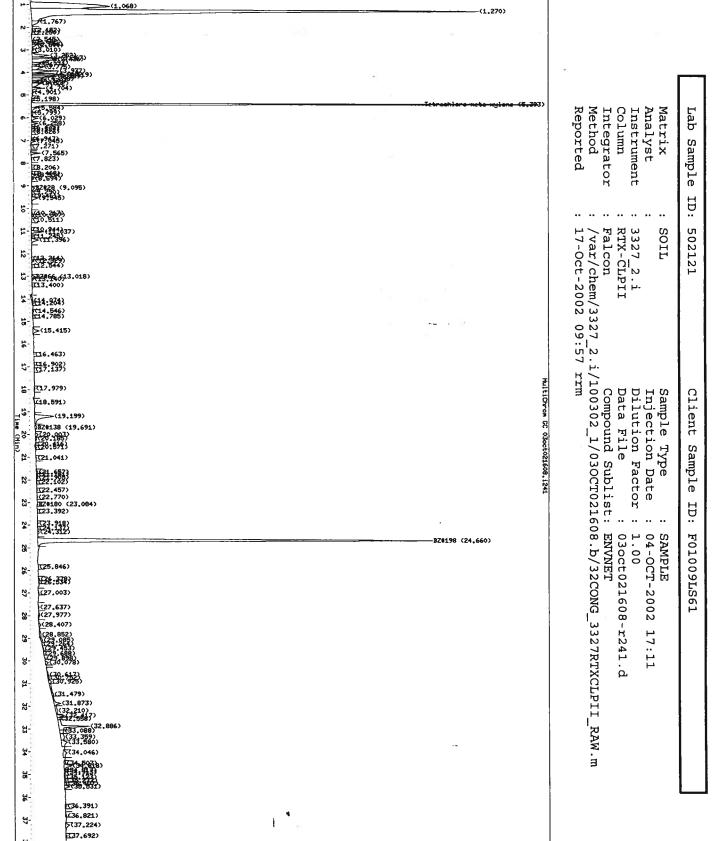

H - User selected alternate compound hit

M - Peak manually integrated or manually identified

R - Peak fails recovery
U - User disabled peak ID: either peak quantitates below reporting limit or peak identification not confirmed on second column

Flags: A - Peak quantitates above calibration range

a - Peak quantitates below reporting limit

H - User selected alternate compound hit

Reported: 10/17/2002 09:57 rrm

 $\ensuremath{\mathrm{M}}$  - Peak manually integrated or manually identified

R - Peak fails recovery

U - User disabled peak ID: either peak quantitates below reporting limit or

peak identification not confirmed on second column
